THE PROBLEM OF LONG CONTINUED, LOW GRADE FEVER

HOBART A. REIMANN, MD

Associate Professor of Practice of Medicine and Clinical Medicine,
Jefferson Medical College
PHILADELPHIA

The problem of diagnosis in patients with long continued, low grade fever occurs far more commonly than would be led to believe by the few studies that have been reported dealing exclusively with the subject. A serious question exists regarding the range of body temperature found in normal persons and the limits beyond which disease may be suspected. The present study with persons whose maximal or whose average temperature is higher than the accepted normal at the time of Wunderlich, sixty-five years ago, has shown that a certain proportion of normal persons may have temperatures regulated at levels slightly higher than 37 C (98.6 F).¹ There are, on the other hand, clinicians who are skeptical of this view and believe that any rise above this level should be regarded as evidence of actual disease.² They are correct in pointing out the danger of regarding normal thermuria as a diagnostic refuge when no cause can be found for persistent low grade fever. Yet it seems likely that a fixed level of body temperature represents the normal for all. Differences are known to exist in a number of measurable factors concerning any group of individuals. Variations in pulse rate, respiratory rate and blood pressure, for example, are too well known to require further mention. There is, therefore, serious basis for the prediction of the existence of persons whose temperature may be regulated normally at levels slightly under or slightly over 37 C (98.6 F). When a curve is prepared to show the percentage probability of occurrence of oral temperature in a normal population as shown in chart 1, it appears that the oral temperature of about 60 per cent of normal adult persons is between 36.8 C (98.2 F) and 37.2 C (98.9 F), spread beyond these levels is considerable in both

directions, with the incidence of probability diminishing toward extremes of 36.1 C (97 F) on the one hand and 37.9 C (100.2 F) on the other.

Several investigators who have studied prolonged, low grade fever as a diagnostic problem have selected for discussion hospital records or records from their practice.³ Many patients were obviously ill and the temperature ranged between 37.8 C (100 F) and 38.4 C (101 F), which is beyond the predicted normal range. In a large proportion of such cases, diagnosis of infection or neoplasm was eventually made. These results suggested that temperature persistently exceeding 37 C (98.6 F) is of serious import and only under the most exceptional circumstances should it be regarded as normal in any given case. In the present investigation the problem was approached from a different point of view, and different impressions were gained. A deliberate attempt was made to seek out individuals with prolonged subfebrile temperature, rarely exceeding 37.2 C (100 F), and to study each case intensively at repeated intervals over long periods. Of the sixteen patients thus far studied, all were women, ten of whom were unmarried. Two general types have emerged: (a) five patients who had no complaints and were regarded as otherwise healthy and (b) eleven who were regarded as neurotic, who had a multitude of bizarre complaints for which no cause could be found after prolonged search with all the diagnostic methods available.

In studying this group of persons, efforts were made to determine whether hyperthermia represented normal temperature or whether actual fever and underlying disease were present. The problem was especially difficult in neurotic patients who, in addition to hyperthermia, had numerous other complaints. A number of infectious and other diseases were considered as possible causes for the fever, the more common of which were tuberculosis, undulant fever, rheumatic fever, syphilis, neoplasm and brain disease.^{2b} The influence of various endocrine gland disturbances on regulation or alteration of the temperature also was considered. There is no doubt that both the thyroid and the adrenal glands may play a role. Most observers who have studied the temperature in relation to the menstrual cycle have noted a rise in the level during the latter half of the intermenstrual period, often to fever levels.⁴ Fekete,⁵ who recently reviewed some of the literature on the subject, suggested over-secretion of the anterior lobe of the hypophysis as the

cause, and empirical attempts⁶ have already been made to control the premenstrual temperature rise with glandular substances.

In studying these patients, aside from a careful history and long and repeated clinical observation and examination a number of other factors and data were especially helpful in diagnosis. They included registration of several temperature readings daily for at least a month at repeated intervals morphologic and

Fig. 1—Curve of the probable incidence of average normal oral temperature constructed from a table prepared by Dr. Frances Vanzant.^{1b}

numerical studies of blood cells, determination of the blood sedimentation rate, Wassermann reaction and various agglutinins, intradermal tests for tuberculosis and brucellosis, basal metabolic rate, constancy of body weight and any special procedures as dictated by the individual case. The drug tests of Hollo and Hollo-Weil,⁷ depending on the antipyretic effect of certain drugs on fever of infectious origin and of opium in

infection no abnormalities aside from subfebrile temperature were detected during several periods of observation. In the five years following my first examination the patient has been well except for occasional colds. Her temperature still registers over 37 C (98.6 F) as it has done for twenty-four years.

CASE 2—Mrs. M. Z. (record furnished through the courtesy of Dr. Renben Johnson) was operated on in 1932 for acute appendicitis followed by pain in the abdomen probably due to oophoritis, with leukocytosis of 12,000. The pain and leukocytosis disappeared after six months. Ever since the operation she noted slight fever in the afternoon averaging 37.6 C (99.6 F), and almost always lower in the first half of the intermenstrual period. There were no complaints and no abnormal physical signs were found except the elevated temperature. The Widal test, agglutinins for Brucella, numerous roentgenograms of the chest and sinuses and urinalysis were negative and the basal metabolic rate was normal. In May 1936 her temperature measured during a period of two weeks averaged 37.3 C (99.2 F). The patient is well and carries on her daily work without difficulty.

CASE 3—Mrs. M. A. aged 28, first noted an elevation of temperature in 1932 during the course of an examination to determine the cause of dysmenorrhea. Because the temperature reached 37.2 C (99 F) or over daily, her physicians examined her repeatedly for tuberculosis without positive results. The temperature when measured was often higher than normal and caused the patient considerable apprehension. There had been any cough, loss of weight or other symptoms except those of dysmenorrhea which have improved since 1932.

The patient by request entered the hospital for two days where an examination revealed no abnormalities. All laboratory studies were negative. The patient then returned home to her usual work and recorded her oral temperature twice daily for fifty-six days, including two menstrual periods. With only two or three exceptions, the afternoon temperature exceeded 37 C (98.6 F), but was never above 37.6 C (99.6 F). The typical rhythmic relation to the menstrual period was observed as shown in chart 2. During the first half of the intermenstrual period the average temperature was consistently lower than that during the latter half.

CASE 4—Miss J. A. aged 17, had an ovarian cyst removed in February 1934, following which she promptly recovered. In July she became tired and sleepy in the afternoon.

Fig. 2—Fifty-six day oral temperature record including two menstrual periods (shaded area) in case 3. The rhythmic relationship of the temperature to the menstrual cycle is shown. The temperature level is generally lower during menstruation and the first half of the intermenstrual period.

depressing normal temperature, have been helpful but like all other tests they are not infallible.

To illustrate the problem of diagnosis in cases of prolonged fever a few illustrative reports are given.

PROLONGED FEVER IN OTHERWISE NORMAL PERSONS

CASE 1—Miss B. E., aged 31 had been regarded as a potential invalid with possible tuberculosis for nineteen years because of persistent low grade fever. After a complete exam-

³ This case was reported in detail previously. Kermann H. A. (a) Basal Hyperthermia, J. A. M. A. 99: 1862 (Nov. 26) 1932. (b) Basal Hyperthermia. Arch. Int. Med. 55: 992-994 (May) 1935.

August a physician found her temperature to be elevated and instituted a search for the cause. The temperature was found to be elevated daily, usually between 37.2 C (99 F) and 37.6 C (99.6 F) rarely reaching 37.8 C (100.1 F). No symptoms were noted except "feeling a little warm" when the temperature was highest. Correction of rather marked secondary anemia by appropriate medication relieved the asthenic symptoms completely. She was given compound solution of ephedrine for two weeks without any effect on the temperature level. Her systolic blood pressure on several occasions was reported as 160, 140 and 146. The menstrual period was normal. December the left maxillary sinus was punctured twice to avail. The patient was referred to the University Hospital by Dr. Herman Drill in March 1935 for further study.

On physical examination she appeared to be normal and robust. No physical or mental abnormalities were detected. The pulse rate was 96 per minute, the blood pressure was 110 systolic and 96 diastolic. All roentgenographic studies

tests with the exception of the basal metabolic rate determination, were normal. The latter was recorded as -23 and -33 per cent of normal, while the temperature was 37.2°C (99°F). Desiccated thyroid in an amount of 0.12 Gm per day was given, beginning March 17. Twelve days later the metabolic rate was -12 per cent and in April it was -17 per cent and 4 per cent. The temperature level was uninfluenced but the pulse rate was somewhat increased.

The diurnal temperature was measured at intervals of two hours and with one exception exceeded normal during the day, varying between 37.2°C (99°F) and 37.7°C (99.8°F). On three days it reached 37.8°C (100°F). The day on which the temperature remained low she had received powdered opium 0.12 Gm and had slept most of the time. On the preceding day she was given aminopyrine 1.8 Gm without any lowering of the temperature level. On two days when the temperature measured 37.6°C (99.6°F) she was obliged to climb and descend five flights of steps repeatedly for fifteen minutes. The result was paradoxical, on both occasions the temperature dropped to 36.7°C (98°F) after forty-five minutes. Epinephrine chloride 0.5 cc of a $1:1,000$ solution, given hypodermically apparently caused an elevation in the temperature.

Fig. 3—Oral temperature on consecutive days in case 4. A drop in temperature following exercise, the ineffectiveness of aminopyrine in lowering the level, a suppression of temperature by opium, an elevation caused by epinephrine and two control days in which no tests were made are shown.

level. Histamine 0.5 mg had no effect. The tests are illustrated in chart 3. No changes were noted in relation to the menstrual period. Miss V was seen again in April 1936. She was well, without complaints, but the temperature measured over a week's time reached 37.4°C (99.4°F) daily.

CASE 5—Mrs. P. J., aged 26, was referred by Dr. Lawrence Cady for determination of the cause for prolonged low grade fever. She gave birth to an infant in February 1935 and was troubled with cystitis, which lasted about two weeks and disappeared. In December the patient noted that she tired easily on exertion. She lost 7 pounds (3.2 Kg.) but regained it rapidly. These symptoms were attributed largely to overwork and exhaustion. Rest in bed was found to relieve them. Tuberculosis was suspected. She measured her temperature and found it to vary from 37.4°C (99.4°F) and 38.1°C (100.6°F). She then recorded her temperature daily and noted herself that the level was generally higher in the week preceding her menstrual period and lowest during the week following. Her menstrual history is normal.

On examination the patient was found to be well developed and robust. She made no complaints except of tiredness after housework. No abnormalities were discovered. The pelvic organs were normal. The pulse rate averaged 72 beats per minute and the temperature during three days of observation under bed rest reached 37.3°C (99.2°F) only once. Subcutaneous injection of 0.5 cc. of a $1:1,000$ solution of epinephrine hydrochloride caused an elevation of the pulse rate but did not influence the temperature. The blood count, sedimentation time and repeated urinalyses were negative. The Mantoux test with 0.1 mg of old tuberculin was negative. The basal metabolic rate was -7 per cent.

The patient continued to record her temperature four times a day for forty days at home. The temperature at 7 a.m. was always subnormal, with the lowest levels recorded a week after the menstrual period. The afternoon temperature without exception ranged between 37.2°C (99°F) and 37.6°C (99.6°F), never exceeding the latter level.

The five cases just described concern persons in good health and without complaints who are able to under-

take their daily tasks without difficulty but who have diurnal oral temperatures which persistently reach levels higher than 37°C (98.6°F). Because of this tuberculosis was suspected in each instance.

PROLONGED FEVER IN NEUROTIC PERSONS

CASES 6, 7 and 8—(Misses R. L., K. U., and E. R.) were reported in detail previously.^{8b} Miss K. U., after leaving the hospital in April 1934, has returned to the outpatient department seventy times to date, visiting various divisions for various complaints. No new information was recorded. Her temperature still registers between 37.2°C (99°F) and 37.6°C (99.7°F), at which level it has apparently been for nine years. Miss E. R. was visited at her home in April 1936. Her complaints were unchanged and her temperature measured 37.2°C (99°F). Elevated temperature was first noted sixteen years ago.

CASE 9—Miss H. M., aged 30, apparently had some emotional disturbances of undetermined nature while in school in 1924. Her parents were in financial straits and were partially dependent on the patient for support. She was obliged to earn

money by teaching in addition to her schooling. Within the past few years it was said that her physiognomy had changed considerably, involving considerable loss of attractiveness and the development of a beard and hair on the extremities. Of late she has shunned male companions and has withdrawn from old friends of her own sex.

In December 1934 while under a heavy teaching load she developed some mild infection characterized by transient diarrhea, a fainting spell, and periods of sweating. Her temperature was found to be 37.8°C (100°F). Since then the patient has not been able to work. Her physician regarded her case as nervous exhaustion. She went to bed, where she remained eight months, complaining of intense weakness to the extent of being unable to lift food to her mouth. She also noted sharp pains and pulling sensations in the heart and tightness in the neck when excited. She was admitted to the University Hospital in July 1935.

On physical examination the patient was fairly well developed and was not remarkable except for slight hirsutism of the face and extremities, a greasy skin and facial acne. The hands and feet were cold and moist. There was marked dermatographia. Psychiatric examination revealed a psychoneurotic personality. Otherwise no abnormalities were found. The laboratory and x-ray studies were negative. The pulse rate usually ranged between 90 and 100 and occasionally rose to 140 after the exertion of sitting up, for example. The temperature when registered at intervals of two hours during the day for the seventy-five days of observation without exception exceeded 37°C (98.6°F) in the daytime, averaging 37.5°C (99.5°F) and rarely reaching 37.8°C (100°F). Exercise or menstruation had no effect in elevating the level, but powdered opium depressed the usual high afternoon level to 37°C (98.6°F). Aminopyrine 1.3 Gm did not lower the level.

The patient recorded her temperature for six days in April 1936. It registered daily between 37.2°C (99°F) and 37.6°C (99.6°F). By this time she had regained considerable strength and was able to walk short distances.

CASE 10—Miss E. E., aged 23 began to have at times a peculiar feeling of twitching and numbness in the muscles of her back in 1930. These attacks were frequent at first but

gradually diminished. She was nervous, worried, irritable, cried easily, was unable to sleep and had severe orbital headaches. In May 1935 the headaches and nervousness became worse. Later she noted an inability to "make her hands do what she wanted them to do" and there was a prickling sensation of the forearms. She began to fear insanity. These symptoms she stated, were relieved by a tonsillectomy in August. In September she complained of indigestion and palpitation of the heart. A spinal puncture in October revealed normal spinal fluid. No refractive errors were found in her eyes. About this time her physician noted an elevation of temperature and requested her to keep a record for two months. This was done and with one or two exceptions the temperature rose to levels over 37.2 C (99 F) daily and exceeded 37.8 C (100 F) only once. The patient had been obliged to work hard for the past few years as a domestic servant and waitress, in addition to keeping house for an invalid father. She was well adjusted socially and rated high in high school work. The patient entered the University Hospital for study in December.

Her chief complaint was nervousness, indigestion, irregular menstruation and vague pain in the lower portion of the abdomen. Her menstrual periods began at 12 years and were always irregular and sometimes painful. Intervals between the periods which lasted for a variable number of days, varied from two to twelve weeks. On physical examination she was found to be intelligent and cooperative without undue nervousness. She appeared to be healthy and robust. Aside from marked dermatographia, cold moist extremities and temperature higher than normal, no abnormalities were discovered. Neurologic examination was negative. Her pulse rate averaged 80 beats per minute and the blood pressure was 100 systolic and 80 diastolic, rising to 110 and 85 respectively one minute after her hands were immersed in ice water. The blood, urine and gastric contents were normal when tested. The sedimentation rate was normal. The basal metabolic rates determined in December were -35, -30, -6 and -27 per cent. She was given 0.18 Gm of desiccated thyroid gland daily for nine days, after which the basal metabolic rate was still -27 per cent. The dose was doubled to 0.35 Gm daily for two weeks after which the rate rose to -7 and -9 per cent. From January 22 to January 29, 0.54 Gm given daily caused the metabolic rate to rise to +6 per cent. In spite of the large dosage, her average pulse rate was increased only 10 beats per minute; there were no unusual symptoms and no influence on menstruation or on the temperature level. The patient continued taking desiccated thyroid 0.36 Gm daily for three weeks after leaving the hospital. The temperature maintained its usual level.

CASE 11—Miss E. McG., a student, aged 15, after having visited a series of physicians was sent to me for study in October 1935 by Dr. Moses Barron. In 1930 at the age of 10 the patient was taken to a tuberculosis clinic because of persistent elevation of temperature above normal, discovered during routine periodic public school examination. There was in addition a continual nonproductive cough. Her school life was then restricted because of a suspicion of tuberculosis. Four Mantoux tests performed at this time were negative and no other evidence of tuberculosis was ever found. Her temperature was more or less continually elevated, reaching 37.6 C (99.6 F) and sometimes 38 C (100.4 F). In 1935 she complained of frontal headache. The frontal sinuses were washed and the mastoid process was opened without any abnormalities being found and with no relief of headache. Incidental history concerns the fact that the patient was abandoned as an infant and was raised by sympathetic foster parents. The patient is aware of the facts and is distressed by them. Her menstrual periods are normal and regular. Her only complaints on questioning were frontal headache, cough and deafness in the left ear. She was unaware of elevated temperature except by thermometer. On examination she appeared to be nervous with constant twitching and a short, nonproductive forced cough. These symptoms were always more marked under nervous tension. The patient was later informed that her cough was unnecessary since no cause was found to account for it. The cough promptly ceased and has not recurred to date seven months later. A slight error of retraction was corrected with relief of the headache. Her pulse rate averaged 80 per minute. Aside from a slightly enlarged thyroid gland, no other abnormalities were detected. All laboratory tests the

Mantoux test and roentgenograms were negative. A psychometric report by Dr. Hathaway revealed an intelligence quotient of 110. Dr. R. C. Gray, the consulting psychiatrist, regarded the condition as a functional neurosis. The temperature was elevated daily, the peaks averaging about 37.5 C (99.5 F). There was no rhythmic relationship to the menstrual period. Epinephrine, aminopyrine, opium and strenuous physical exercise failed to alter the usual level.

Cases 9, 10 and 11 are described in considerable detail to illustrate the type of neurotic patient in whom hyperthermia was encountered. Several other similar patients are under observation whose records for want of space are not given in detail. One (case 12) concerns a student nurse (Miss E. M.) who had noted that her temperature when recorded at times since she entered the training school two years before was slightly higher than normal. She was regarded as suffering from a mild affective disorder. Examination and laboratory tests revealed no other abnormalities. Another patient (case 13, Mrs. M. M., aged 49) had had numerous abdominal operations. In this case hyperthermia was associated with basal metabolic rates varying from -22 to -38 per cent. Dessicated thyroid substance 0.18 Gm, given daily for two weeks, failed to raise the level or to influence the temperature. Three other patients presented symptoms and changes similar in many respects to those described. All were regarded as neurotic individuals by the psychiatrist and by myself. There can be but little doubt that neurosis is the outstanding feature in cases 6 to 13. It is of interest to note that with one exception each patient in this group was unmarried. In some patients, temperature elevation as discovered by thermometry was the chief source of concern, but in most it was noted by the physician in charge and was a minor factor in the case. The hyperthermia had been known to exist for from sixteen months to sixteen years in this group and was still present in each patient when recently measured. Each patient had visited many different physicians and many different diagnoses had been made. Tuberculosis had been suspected in each case at some time, and three patients had been confined needlessly in tuberculosis sanatoriums. After careful study at repeated intervals, no cause was found to account for fever.

Two patients, not included in this series, were studied because of prolonged fever. In one, a man aged 46, there was unmistakable evidence of infection with pallor, malaise, loss of weight and an increased blood sedimentation rate, although the leukocytes were normal and the fever failed to respond to aminopyrine. This patient had had prostatitis and a urethral discharge for years. Several months after examination, an acute prostatic abscess developed. Another patient, a woman aged 30, had had fever for six years, occasionally reaching 39.5 C (103 F). She complained of weakness and loss of weight. There was continual soreness and distress in the right hypochondrium and epigastrium. The leukocytes were normal but the sedimentation rate was 100 mm in the first hour. Aminopyrine caused a prompt drop in the temperature from 37.9 C (100.2 F) to 35.2 C (95.4 F). The Wassermann reaction was found to be + and after administration of potassium iodide the temperature returned to normal and recovery ensued. The diagnosis was syphilis of the liver.

COMMENT

In the sixteen cases reported attempts were made to show that the maximal or the average oral temperature of certain persons otherwise physically well as far as could be determined is higher than the usually

accepted normal level. In most instances, hyperthermia was first detected when the temperature was measured because of some incidental infection or disease or in routine physical examination at school. It is probable that in many instances hyperthermia was present long before its detection. Persistence of the level over the normal initiated prolonged observation and search to determine the cause. In the five women regarded as normal who were free from complaints, the "fever" caused more apprehension to the person's family or physician than to themselves. It is difficult to escape the conviction that the temperature of these persons was normal for them, especially in case 1, in which hyperthermia has existed twenty-four years.

The diagnostic difficulties were multiplied in neurotic patients as illustrated in the cases reported. Each patient represented a separate problem. Their numerous complaints necessitated careful and prolonged search to rule out the presence of underlying organic disease. Especial consideration was given to undulant fever because of the long duration, subfebrile temperature and neurotic symptoms known to characterize the occasional case. Tuberculosis is less likely to persist for years without becoming manifest.²⁴ In some cases, even after complete studies were made without detection of physical abnormalities and the patient was informed of the facts, the complaints persisted, and advice was sought elsewhere as in cases 6, 7 and 8. The fact that temperature at fever levels persisted, in one case as long as sixteen years, suggests that hyperthermia in certain patients is part of the neurotic syndrome.⁹

Of interest was the low basal metabolic rate frequently found while the temperature was higher than normal, especially in cases 4, 16 and 13. Thyroid gland medication failed to alter the rate significantly, nor was the temperature influenced by the drug, as in the case reported by Lee.¹⁰ None of these patients were myxedematous, each had menstrual disturbances and may perhaps be classed with the type of patient recently studied by Haines and Mussey,¹¹ although improvement after thyroid gland medication, as noted by these observers, did not occur.

As indicated in this study, it is of considerable practical importance to determine whether persistent temperature at levels higher than normal in a given patient is to be regarded as normal or whether actual organic disease is present. It is a serious matter, for example, to regard a patient as tuberculous and prescribe sanatorium care (cases 1, 7 and 11) on no other ground than that of fever. Furthermore, allaying the fear of nonexistent disease in patients with hyperthermia has resulted in a striking improvement in the emotional state of a number of my patients. Nevertheless, it should be reemphasized at this point that every possible diagnostic means should be employed in patients of the type here described to detect underlying, obscure disease before the temperature is regarded as normal or as part of a neurosis.

The question may be raised whether the term "habitual hyperthermia" or any term need be applied to the type of patient described. There appears to be no more reason to do so than to apply the term "habitual bradycardia" to normal persons with an average pulse

rate of 60. They simply represent a class of individuals whose average temperature levels fall within the upper limits of the normal range of variation.

SUMMARY

A group of sixteen women whose oral temperature reached levels slightly higher than 37 C (98.6 F) for years was studied to determine whether or not infection or other organic disease was present to cause the fever. Five of those examined were apparently normal healthy women, but the rest were regarded as neurotic. The temperature in each case reached levels over 37 C (98.6 F) daily for months or years but seldom exceeded 37.8 C (100 F) unless actual infection or other known cause intervened. Complete physical examination, long and repeated observation, roentgenographic studies and laboratory and biologic tests failed to reveal an underlying cause for the hyperthermia. It was concluded that a certain proportion of normal individuals have temperatures regulated at levels slightly higher than 37 C (98.6 F) and that temperature at these levels is often found in neurotic persons.

1025 Walnut Street.

ABSTRACT OF DISCUSSION

DR. A. C. ERNSTENE, Cleveland. Dr. Reimann has emphasized that his observations are not intended to offer a common diagnostic refuge when one is confronted with the problem of a long continued unexplained fever. The cases he has studied belong to a relatively small group, and in this group the procedure of repeated periodic observations that he has followed should be adopted. In the study of prolonged low grade fever, the erythrocyte sedimentation rate is of great value. As long as the rate is elevated, fever must be assumed to be due to an organic cause. On the other hand, a normal sedimentation rate does not exclude the presence of organic disease. In many individuals, for instance, in whom the weight of evidence indicates the presence of chronic undulant fever, the erythrocyte sedimentation rate is normal. In the study of prolonged low grade fever, special consideration must be given to the possible presence of chronic brucellosis, for the diagnosis of this condition is frequently difficult. Specific agglutinins may no longer be present in the blood serum when the patient is first seen. The intradermal test with undulant fever vaccine is a helpful diagnostic aid, but the results must be interpreted with care. The opsonocytophagic index is also of value. The length of time Dr. Reimann has had his patients under observation is sufficient to exclude tuberculous disease as a possible cause of the elevation in temperature. When tuberculosis is responsible for prolonged low grade fever, the true state of affairs either becomes manifest within a period of a few months or the fever subsides. In the past, considerable attention has been paid to focal infection as a possible cause of persistent low grade fever. Authenticated instances, however, in which the removal of foci, such as infected teeth or tonsils, have resulted in disappearance of the fever, are suggestively uncommon. It is probable, therefore, that focal infection does not cause prolonged low grade fever. Finally, the question arises whether one is justified in making a diagnosis of physiologic fever and dismissing the patient. In the absence of symptoms, I believe that such a course may be safely adopted, provided the patient has been under observation for not less than one year.

DR. RUSSELL M. WILDER, Rochester, Minn. Dr. Reimann has made clear that the temperature of the normal human being, in health, fluctuates to a certain degree. This, of course, is not surprising. There are no physiologic constants that are really constant. The rate of the heart, the rate of respiration and the basal metabolic rate, which are called constants, all show more or less fluctuation. It would seem, however, that the range of fluctuation in the case of temperature is less than in these other physiologic constants, and that therefore when deviations are seen from what are regarded as normal temperature one ought to be extremely hesitant to conclude that such a deviation represents a normal fluctuation. The temperature of the body

is a resultant of a rate of production of heat by metabolism and the rate of its elimination. Either of these processes may be affected by peripheral influences, but both of them in the case of warm blooded animals, are under the regulatory control of some center or centers in the brain or brain stem. Thus if the spinal cord is severed in a warm-blooded animal, the thermostatic regulation exercised from above disappears and the homeothermic organism becomes poikilothermic. I am not informed whether the brilliant investigations of Dr Ranson at North western with the Horsley-Clark stereotaxic instrument, by means of which he is exploring various regions in the sub-thalamic region have revealed the location in the diencephalon of a thermic center but that such a center exists is evident from the frequent occurrence of fever after surgical operations on the head and after other injuries to the base of the brain. Also the effect of the antipyretics is accounted for by central action. Occasionally cases are encountered in which hyperthermia follows infectious lesions of the brain such as those of epidemic encephalitis or poliomyelitis. In such cases the general toxicity of the infecting organism is not such as to be responsible for causing much fever, and yet fever occurs and may persist for months or even years. It is recognized that encephalitis may leave no residues and frequently does not leave the characteristic Parkinson type of residue. We ought to think of the possibility of lasting injuries to thermostatic centers in the brain stem by previously unrecognized encephalitic infection as an explanation at least of some cases of hyperthermia of supposedly normal individuals.

POLIOMYELITIS

PRESENT KNOWLEDGE AND ITS BEARING ON CONTROL

J. P. LEAKE, M.D.

Medical Director U. S. Public Health Service
WASHINGTON, D. C.

On Saturday, May 14, 1796, just one hundred and forty years ago today, Dr. Edward Jenner performed his first vaccination against smallpox. It is fitting that we pay tribute on this date to this most successful of measures in specific disease prevention while we are considering the prevention of a disease in some respects similar and in some very different from the disease against which Jenner led the way. The slow development of Jenner's thoughts and work in his campaign may give us heart when we consider the present lack of effective control of poliomyelitis. Neither should we be discouraged if some of our steps are false. Jenner was badly mistaken in more than one regard and the fierce devotion with which the friends of his procedure fought for every detail of his views has obscured the truth and hindered full prevention. The need for revaccination was combated by Jenner and his direct followers. The credit for setting the world right in this respect cannot be centered on one person though Gold-on in 1804 was probably the first to announce diminution in the protective action of vaccination with time. In 1851 fifty-three years after Jenner's announcement the National Vaccine Establishment of England declared that revaccination was incorrect in theory as it was uncalled for in practice. Even the first description of the immediate or immune reaction on revaccination usually credited to Jenner belongs rather to Jenner's friend James Bryce¹ of Edinburgh whose careful work on vaccination first published in 1802 has been pointed out by Dr. George

Weaver of Chicago. Bryce also described the accelerated or vaccinoid reaction on revaccination, while Jenner's note was limited to an early reaction after inoculation with smallpox itself.

In connection with today's Jennerian anniversary, it might be well to remember that the greatest contribution of this century to the study of vaccination was made by Dr. Clemens Pirquet² of Vienna. He simply observed his vaccinations and revaccinations daily until the inflammation had completely subsided and he recorded them by actual measurement.

Numerically, poliomyelitis is not a large problem in comparison with other infectious diseases. For the last three years for which mortality data are available throughout the registration area poliomyelitis has accounted for only about 800 deaths a year, 'epidemic' encephalitis about 1,000, 'non-epidemic' encephalitis about 1,500, tetanus about 1,200, epidemic meningitis about 1,500, tuberculous meningitis about 2,200, other forms of meningitis about 2,100, erysipelas about 2,000, scarlet fever about 2,500, dysentery from 2,000 to 3,000, diphtheria about 5,000, typhoid about 4,300, malaria from 1,500 to 2,500, whooping cough from 4,500 to 7,500, syphilis 11,000, gonorrhea 1,000, tuberculosis about 75,000, and automobile accidents from 28,000 to 36,000.

As to the number of cases, it has been customary to think that for the greater part of the United States there are in round numbers ten paralytic cases a year per hundred thousand of population, counting as paralytic those with definite localized weakness, even though the weakness might be transient and often not reported. This estimate is based on one of the first house-to-house surveys undertaken of an entire community for past illness³ and on other groups of data all too small or localized to be very reliable. It is to be hoped that this year's health survey⁴ will give a larger body of figures on which a more accurate estimate can be made. In non-epidemic times, reporting is irregular. Except Scandinavia, all of Europe appears to have definitely less of the disease than the United States and the central part of our own country less than the seaboard. Declared cases are fewer in the warmer belts than in the North. One of the most intense epidemics on record was on the equator, on an isolated volcanic remnant called Muro or Pleasant Island 8 square miles in area and holding 2,300 people, 200 miles from the nearest still smaller island 2,500 miles from Sydney, Australia, and 4,000 miles from Hong Kong. There were 700 cases, a rate of 30,000 per hundred thousand but only a part were paralytic. The natives chiefly were affected, but the Chinese and Europeans who were working for a British phosphate company and had come in contact with the outside world were almost completely spared. In contrast to the usual age distribution of poliomyelitis only a few patients were under 12 years of age. This epidemic and a similar tendency toward more intense incidence and occurrence among older age groups in rural epidemics than in cities, form part of the reason for believing that immunization without obvious infection is a valuable prophylactic which is missed by allowing our children to lead too segregated a life in non-epidemic times.

From the spotty fashion in which cases appear even in epidemics, usually without traceable relation to one mother or to a credible common source of infection, it becomes almost impossible to formulate a theory consonant with the observed distribution of the disease which does not include carriers as the most important means of spread. If the effective carriers were persistent, it would appear that more frequently a trail would be left through a series of cases pointing with suspicion to one person. In this as in other angles of the disease, we wish that the light were clearer, but we should not desist from acting on the basis of such light as is available.

The marked seasonal wave of poliomyelitis has suggested two modes of spread—by the gastro-intestinal tract, as in some other infections of warm weather, and by insects. The frequency of gastro-intestinal symptoms at onset has also suggested the former mode of spread. Evidence from nature would be hard to secure to refute this, but recent work in various hands with monkey cord virus gives strong support to the idea that the infection is transmitted in nature through the olfactory portion of the nasal mucosa and in fact through the nerve cells themselves. As negative evidence against gastro-intestinal infection the experiments of Clark, Roberts and Preston⁶ are persuasive. Susceptible monkeys could not be infected by being fed virus or by having it injected into an isolated intestinal loop, yet the feces of these monkeys were later proved infectious.

The fact that an epidemic of typical intensity, spread and clinical characteristics occurred during a West Virginia winter when observations could eliminate ordinary summer insects as vectors is likewise persuasive that such insects play no necessary part in the spread of poliomyelitis in spite of its usual summer prevalence.

It is generally believed, on the basis of repeated isolation of a filtrable virus from the affected spinal cords in human cases, causing typical symptoms and lesions in monkeys and monkeys only, by intracranial inoculation and particularly by intranasal application, that this ultravirus is the true cause of the disease.

The site of invasion in meningococcal meningitis is believed to be grossly similar to that in poliomyelitis, and both diseases are believed to be spread largely by carriers, yet the one disease is caused by an easily visible invader and the other by an ultravirus. Most infections with ultraviruses are not only intracellular but propagated in the fixed cells of the body. This forms an array for combat different from that presented by a parasite of the surface the fluids or the wandering cells of the body. It is probable that very minute bodies, in addition to having the power to enter cells, rather than merely entering fluids and intracellular spaces, are taken up very rapidly. It is also possible that immune substances in the body fluids which occur naturally or are stimulated artificially are of less account in actual defense than when the microscopic foe is more visible.⁸ Such considerations of special affinity for cells on the part of ultraviruses has led Goodpasture⁹ to remark that "it is especially important for investigations to be undertaken in attempts to alter the cellular media by chemical means in the hope of modifying the course of an infection by viruses or of

preventing infection completely by rendering normally susceptible cells artificially insusceptible."

To what practical action, then, does this consideration of the disease lead? Obviously against any radical or otherwise disastrous procedures. In spite of the general dread, parents should realize that the numerical chance of affliction is small. Reasonable precautions against needless human contacts during epidemic seasons are wise. So far as a comparison with control individuals pointed, in Los Angeles in 1934 there was no general danger from swimming pools or beaches. A history of overexertion preceding an attack has often been noted in cases of poliomyelitis. That this may be an important hint for prevention is suggested in the Los Angeles epidemic by the fact that with comparable control individuals such a history could be obtained much less frequently than with individuals attacked by the disease.

Full reporting, in this as in every other disease, is the first step in organized control of the situation. In this connection it is strongly advised that physicians, in reporting each case, report it as paralytic or non-paralytic, that is, whether or not any definite local weakness can be detected. Within three days after the first symptoms most patients who are to be paralytic have given evidence of weakness, and in the others the report can be amended. Every case should be designated as paralytic or nonparalytic. Only in this way can comparison be made from week to week, place to place or season to season. In the 1916 epidemic and preceding it, all but a few reported cases were paralytic. In 1931, 70 per cent of the New York City cases were paralytic, in 1935 about 50 per cent in Albemarle County, Va., in the same year, about 14 per cent, in Denmark in 1934, 14 per cent with only 3 per cent in Haderslev County.¹⁰

In addition to these discrepancies, the recent recognition of conditions similar to nonparalytic poliomyelitis but of different causation, calls for such differentiation. The Economo type A encephalitis still occurs, as well as the so-called summer encephalitis, or type B. Lymphocytic choriomeningitis, the virus of which was discovered by Armstrong¹¹ and also found by Rivers¹² and Traub¹³ may easily cause confusion. Still more similar to nonparalytic poliomyelitis is the meningo-encephalitis, 150 generally mild cases of which occurred last summer within about six weeks in a town of 10,000 in south-central Pennsylvania. Armstrong and Wooley¹⁴ have found this different immunologically from lymphocytic choriomeningitis in that the serums from recovered patients have no protective power against that virus. The possible presence of all these confusing conditions in one locality is reason enough for such differentiation as is practicable. To revert to the Jennerian anniversary and Dr Pirquet's contribution. Pirquet merely observed completely, without prejudice, and recorded from day to day. So by detailed watch of the muscular strength not only is accuracy of diagnosis enhanced in poliomyelitis but treatment is improved and perhaps some day prevention may be achieved. In summary, though undue alarm should be allayed in the prevalence of this

disease in epidemic intensity, it is reasonable to abstain from unnecessary contacts, even with the well, to guard the especially susceptible ages against excessive strain, and to report suspicious illnesses promptly, but with a differentiation as to whether they are paralytic or non-paralytic. For the present the prospect of the discovery of a vaccine that will be highly preventive and at the same time relatively harmless is small, and chemical prophylaxis by means of local applications should be considered still in the trial stage.

ABSTRACT OF DISCUSSION

DR. JAMES D. TRASK, New Haven, Conn. Dr. Leake, in the epidemic on the island of Nauru, was a strain of the virus of poliomyelitis recovered? My experience with poliomyelitis has been gained by following Dr. Leake's footsteps, that is, by making house to house visits in field studies and this work has been done with Dr. Paul. Our first experience was that it was relatively easy to get the virus from examples of abortive poliomyelitis, provided nasal washings were taken the first two days of the disease. Thus, in 1931 we had two successes out of five attempts. Since then we have tried with vigor in each epidemic, to detect the virus in nasal washings from all types of patients acutely ill with poliomyelitis and have had only one more success. In the literature there are eleven satisfactory examples of recovery of the virus from patients and three examples of the recovery of the virus from the nose and throat of 'healthy carriers', therefore there is little direct experimental evidence that this disease is actually transmitted by means of direct contact from nose to nose in man. Many people have said that the lack of success in finding the virus, in patients and contacts, is due to the lack of satisfactory methods. This may be the explanation but the last time we recovered the virus from nasal washings Dr. Paul saved the washings in glycerin, and as late as 100 days from being collected a mere flock of glycerolated mucus was sufficient to infect monkeys with poliomyelitis. So one can say that in certain instances the method is extremely good and one should question very much whether it is satisfactory to keep on thinking that nose to nose is the method of transmission. It is true for example that, in yellow fever nose to nose transfer is possible with the virus under laboratory conditions.

DR. SIDNEY D. KRAMER, Brooklyn. Dr. Leake's figures giving the fatalities of the various infectious diseases bring out most clearly the relative importance of these diseases when compared with poliomyelitis and should serve to allay much of the fear of this disease. In order to account for the widespread immunity in the normal population the widespread dissemination of virus through the agency of healthy carriers has been assumed. This concept was recently supported by the detection of the virus in the tonsils and adenoids of a 2½ year old child who had not been in contact with a case. Immunization in the normal population is therefore apparently accomplished through the so called subclinical route, much as in diphtheria. Although a number of routes for the entrance of the virus has been suggested, both the experimental and epidemiologic evidence is overwhelmingly in favor of the intranasal route of infection. The ease with which experimental infection can be accomplished by that route in normal animals as opposed to the difficulties in obtaining infection by the gastro-intestinal route tends to support this as the portal of entry of the virus in the natural infection. At present there is no adequate practical procedure for either preventing or treating the disease. Experiments now in progress seem to hold promise that some procedures for active immunization and passive prophylaxis may be devised. In spite of its relative rareness it would still be good public health procedure to have some method available for active or passive immunization against poliomyelitis. More recently it has been suggested that the use of certain chemicals sprayed into the nostril may act as a barrier against infection. This work is still in the experimental stage and adequate evidence must yet be presented that such chemicals have in themelves no harmful effects on the nasal mucosa following prolonged use. It should furthermore be realized that the most which can be hoped from such a method of protection is to shift the age distribution of the disease. As far as is known individuals susceptible to a

disease remain susceptible throughout life unless actively immunized against it. In essence the outcome of such transient nonspecific protection will be to shift the age distribution of poliomyelitis from an urban type in which infection occurs early in life to a rural one in which exposure and infection tend to occur later in life.

DR. PAUL H. HARMON, Chicago. There is some doubt as to whether the epidemic referred to on the island in the Pacific Ocean was truly an epidemic of poliomyelitis because of the rare and exceptional epidemiologic features involved in that epidemic. Dr. Leake is to be commended for bringing out and urging that poliomyelitis be reported in terms of the three variable types of that disease, namely the paralytic, the non-paralytic and the abortive type. Only in recent years has convincing evidence come out that the nonparalytic and abortive types far outnumber the really paralytic types in the proportion of ten to one. This disease should not be minimized because of the fact that in the average epidemic of poliomyelitis the incidence is only 60 to 70 per hundred thousand of population. In the larger epidemics that of New York in 1916 and in certain Midwest areas in 1917, the incidence reached to from 140 to 160 per hundred thousand all reported in terms of paralytic cases. Recently it has been the idea that a good many of the so-called sporadic and endemic cases of poliomyelitis are a result of an imbalance between the carrier state and infectiousness of the virus for the individual. There is already some definite evidence to support such an idea reported by Avcock in the appearance of several instances of poliomyelitis, which followed after a typical incubation period after removal of the tonsils. The appearance of poliomyelitis with a definite incubation period, following overexertion and fatigue, is a common observation. May that not suggest that there are a number of instances of carriers of poliomyelitis in whom the balance between the infection by the virus and the carrier state may not be upset by overexertion or trauma? There is some question as to whether the finding of neutralizing substances in the blood really means immunity to the disease. A certain number of persons who are Schick negative are still susceptible to clinical diphtheria. There is some experimental evidence to support such an idea, which is as follows. The most significant study is the one by Gordon of the University of Chicago, who found that 78 per cent of monkeys that were immune to the disease (possessed antiviral substances) still did not resist intranasal inoculation. From 30 to 40 per cent of individuals who have recovered from clinical poliomyelitis do not have neutralizing substances in their blood, yet is there a person who would not be willing to state that that person is probably immune to reinoculation, if any one was to attempt it? May there not be many strains of poliomyelitis virus producing human infection? Paul and Trask have already studied a few such strains. It is possible that the strains more adapted to the human being produce paralytic cases while nonparalytic cases may be due to a strain more attenuated than the average. My associates and I were able to isolate from the rectal washings in a nonparalytic case a strain that we had great difficulty adapting to monkeys. As far as we were able to pass it, through three generations, it remained nonparalytic. There is even some experimental evidence to show that serum is of value in protecting individuals passively.

DR. EMIL BOGEN, Olive View, Calif. Can Dr. Leake give some explanation why the California epidemic in the last few years did not apparently conform to the previous epidemics? Ours was apparently highly communicable as we could trace the passage of the infection from one case to another in nearly half of the individuals who were reported in Kern County. Incidentally there were numerous instances in which a paralytic case could be traced to a nonparalytic case or vice versa showing that the different types of the disease are not due to different viruses. In the two years over 0.3 per cent were reported as having poliomyelitis in a population of less than 100,000 and there were twenty five deaths in this double epidemic. In the instances of known contacts in the hospital staff at Los Angeles or those ferreted out by the epidemiologist in Kern County nearly 20 per cent of them developed the clinical disease. I wonder whether this is a different virus and whether the individuals there might be expected to show a high incidence of immune bodies against the poliomyelitis virus previously reported by a greater susceptibility to the new virus found there or whether owing to the isolation and

the location of the country, it might be expected that we have there, and might have in other parts of the country, large communities which are more susceptible to poliomyelitis and therefore likely to have it again in epidemic form

DR. J. P. LEAKE, Washington, D. C. The Nauru epidemic was not reported as an epidemic of infantile paralysis, in fact, Dr. Müller, the German colonial physician who reported it, ruled out infantile paralysis because it was not in infants, for one thing. That was a feature epidemiologically different from our ordinary poliomyelitis. The high incidence is unusual, but it was an unusual place, and a difference from ordinary poliomyelitis could be expected. The other epidemics on what has been called virgin soil have not been as well reported as this one in Guam, for example, and one in the Bismarck Archipelago. One cannot compare them accurately, but they seem similar. Later observations on Nauru Island have been reported and the patients of the 1910 epidemic are described as having typical residual deformities of poliomyelitis. I believe it is not generally appreciated what a great difference in reporting this disease occurs in different communities, not only depending on the physicians but also according to the concern and knowledge which the parents have and the population generally. The virus was not isolated in Nauru and it was not isolated in the Windber epidemic. Practically the first case in the latter was fatal, and there were no other deaths. Dr. Harmon spoke of the balance or imbalance between the carrier state and infection. I can think of no better reason for the seasonal occurrence of poliomyelitis than that the prolonged warmth of summer after the experience of a winter season makes people more susceptible. Dr. Bogen has asked about the relative susceptibility of different large communities year after year. It is still an unanswered problem.

PERIPHERAL CIRCULATORY DISEASES

EFFECT OF ALTERNATING POSITIVE AND NEGATIVE PRESSURE TREATMENTS ON VENOUS BLOOD AND THE SKIN TEMPERATURES PRELIMINARY REPORT

FRANK V. THEIS, M.D.
AND
M. R. FREELAND, Ph.D.
CHICAGO

Alternating positive and negative pressure treatments are of definite clinical value in the treatment of peripheral circulatory diseases.¹ Periodic skin temperature readings indicate that the clinical improvement is accompanied by increased circulation. However, the absence of significant elevations of skin temperatures following individual treatments does not substantiate the belief that clinical improvement is due to increased circulation. More consistent and higher elevation in skin temperatures is produced by vasodilatation as a result of local heat or reflex heat. Still these measures are less effective in producing clinical improvement than is seen with pressure treatments. Landis² found

that 45 C heat to the arms produces maximum reflex vasodilatation of peripheral vessels in the legs. It is evident that pressure treatments alone do not produce maximum vasodilatation. Combining reflex heat and pressure treatments, our routine procedure gives higher peripheral temperature readings than either measure alone, as shown in the accompanying chart. With

Temperature curves. Senile arteriosclerotic peripheral circulatory disease (table 6). Combined pressure treatments and reflex heat (C) produced greater elevation in skin temperatures than could be obtained with maximum vasodilatation due to nerve block (B) or reflex heat alone (A).

maximum peripheral vasodilatation due to the reflex heat, the additional increase in temperature with the combined procedure must be explained on some basis other than vasodilatation. It is apparent that skin temperatures are insufficient to explain the definite therapeutic value of alternating positive and negative pressure treatments.

Clinical improvement and skin temperature changes do not necessarily imply alterations in blood flow. This is especially true with the insignificant temperature changes that frequently follow pressure treatment. With no change in amount or rapidity of blood flow, increased oxygen-carbon dioxide exchange in the tissues might account, in itself, for some increase in surface temperatures. At the same time the improved tissue metabolism would contribute to clinical improvement. It seemed to us that a study of the oxygen-carbon dioxide content of the venous blood would provide more reliable information to explain the effect of pressure treatments than could be obtained by skin temperatures. By correlating the information thus obtained with the skin temperature readings, a better comparison could be made as to the relative value of pressure treatments, direct heat or indirect heat, or combined reflex vasodilatation and pressure treatment such as we use as a routine.

Consequently this investigation was undertaken to determine, if possible, the effect of heat, pressure treatments or a combination of the two on the peripheral circulation. The following program was carried out on twenty-five patients either as controls or as various types of peripheral circulatory disease.

1. Skin temperature readings under controlled conditions before and after all treatments.

2. Oxygen-carbon dioxide gas analyses of the venous blood of the extremities before and after one hour treatment with (a) alternating positive and negative pressure to both lower extremities and 45 C heat to the upper extremities, (b) alternating positive and negative pressure to both lower extremities, (c) 45 C direct heat to both lower extremities or to both upper extremities, (d) 45 C heat to the upper extremity for the reflex effect on the lower extremity.

3 Total body metabolism tests and oxygen consumption per minute before and after one hour treatments with alternating positive and negative pressures to both lower extremities and heat to both upper extremities

PROCEDURE

Skin temperature readings were taken with the Tyco's dermatometer.² The patients rested in bed for one hour with the lower extremities slightly raised to the level

obtained as far as possible from the internal saphenous vein or one of its branches in the upper part of the leg and from the same site before and after treatment. The blood was withdrawn under oil, without the use of a tourniquet, and kept in a refrigerator until examined. Analyses were made as quickly as possible after the blood was withdrawn. In a few instances repeated determinations were made on the same patient. When the condition of the veins made withdrawal of the blood

of the heart. This is the position used in giving the pressure treatments. After stabilization at room temperature one or more skin temperature readings of the toes and feet were taken before and after treatment. All skin temperature readings were corrected for 20 C room temperature.⁴

Gas analyses of the blood were obtained by Van Slyke's manometric method.⁵ The venous blood was

difficult or the patient objected to repeated tests only one or two determinations were made.

Total body metabolism tests were obtained by the Tissot open method⁶ (forty-eight tests on fifteen patients), the Haldane gas analysis being used for oxygen-carbon dioxide determinations. No effort was made to obtain basal conditions. However the patients rested at room temperature for one hour before skin temperatures and metabolism tests were taken. Following one hour pressure treatments to both lower extremities

ities and heat pads (45 C) to the arms it was possible to determine changes in total consumption of oxygen and elimination of carbon dioxide.

Because of the difficulties in getting patients to cooperate in such an extensive investigation, this preliminary report does not include all types of circulatory diseases. The arthritic patients were selected by Dr E E Irons because of neurocirculatory manifestations. He believed that this group might be benefited by improved peripheral circulation.

RESULTS

Skin temperature readings varied with the form of treatment and the type and severity of the circulatory disease. Pressure treatments alone produced the least

Generally the most marked elevations in skin temperatures occurred in the absence of perspiration.

Gas analyses of the venous blood was made before and after one hour treatments on twenty-five patients. A total of 287 determinations were made on seventy-three specimens of venous blood.

Under ordinary conditions the character of the venous blood depends on the amount of oxygen absorbed from the arterial blood as it passes through the capillary bed and on the amount of carbon dioxide eliminated into the blood stream. Normally the arterial blood has from 94 to 96 per cent of its hemoglobin saturated with oxygen. Lundsgaard⁷ found that in resting subjects the venous blood has an oxygen saturation of from 60 to 85 per cent. The more rapidly

significant elevation in skin temperatures (table 2). In this series three patients had decreased readings from 0.2 to 2.5 degrees C and eight had elevated temperatures from 0.3 to 2.7 degrees C. The majority of these elevations were less than 1 degree C. Heat directly applied to the lower extremities (table 3) or to the upper extremities for reflex vasodilatation (table 4) produced more uniform elevation in skin temperatures. One arteriosclerotic patient with severe diabetes had decreased temperatures after both forms of heat therapy. With direct heat a decline of 1.6 degrees C was recorded and with reflex vasodilatation 0.6 degree C. All other readings were elevated 1 degree C or more, direct heat producing a maximum of 2 degrees C and reflex heat 4.6 degrees C. Combined reflex vasodilatation and pressure treatments produced greater elevation in the temperatures than any other form of treatment. Only three of twenty-six determinations showed decreased readings. These declines were accompanied by considerable perspiration.

the arterial blood passes through the capillary bed, the less oxygen is removed and the less carbon dioxide is absorbed per unit volume of venous blood. Accordingly, as the circulation is increased the oxygen-carbon dioxide content of the venous blood approaches that of the arterial blood. This is accompanied by elevated temperature readings. By immersing the forearms in water at 45 C, Meakins and Davies⁸ found that the rate of flow is so accelerated that the oxygen content of the venous blood is practically identical to that of arterial blood. With the flow retarded more oxygen is removed, more carbon dioxide is absorbed, and the temperature decreases.

Local tissue metabolic changes can alter likewise the oxygen-carbon dioxide ratio of the venous blood.

⁷ Lundsgaard C. Studies of Oxygen in Venous Blood. I. Technique and Results on Normal Individuals. *J Biol Chem.* 33: 133-144 (Jan) 1918.

⁸ Meakins J C. and Davies H W. Observations on the Gases in Human Arterial and Venous Blood. *J Path & Bact* 23: 451 (Dec) 1920.

Goldschmidt and Light⁹ observed that sufficiently intense cold reduces the amount of oxygen removed from the venous blood. They attribute this increased oxygen content of the venous blood to decreased local tissue metabolism. Accordingly the same changes in the oxygen-carbon dioxide content of the venous blood are found with either a rapid blood flow or a lowered tissue metabolism. However, increased circulation as a result of vasodilatation or augmented collateral circulation produces a rise in skin temperatures, while decreased tissue metabolism in all probability is accompanied by lowered temperatures. The reverse situation

patients (table 1). All but the controls showed marked evidence of peripheral circulatory disease. In twenty of the twenty-six determinations there was increased oxygen content of the venous blood and, in all but one of these, elevated skin temperatures. The one patient with a decline in skin temperature perspired considerably, as did almost all of this series. In most instances a corresponding reduction in the carbon dioxide content was found. These results are in agreement with an increased blood flow. However, the increased rate of blood flow as interpreted should bear some relation to the increase in

* This patient Mr G had previously had his right leg amputated

also can occur. With increased metabolism more oxygen is used and more carbon dioxide is produced. The same oxygen-carbon dioxide changes are found with a retarded flow. Local temperature readings are decreased with a retarded flow and may be elevated with increased metabolism. Consequently changes in the oxygen-carbon dioxide content must be correlated with the skin temperature changes. With these possibilities we were able to interpret the results of this investigation.

Combined pressure treatments and reflex heat were used for twenty-six determinations on seventeen

peripheral temperatures. This fact could not be correlated with our observations. The first of our control group had only a slight change in oxygen carbon dioxide content, indicating an insignificant increase in rate of flow. With the recorded 6.5 degrees C elevation in skin temperatures it is more probable that the increased oxygen content of the more rapidly flowing blood was almost completely offset by an increased consumption of oxygen, owing to greater tissue metabolism. When the examination was repeated five days later a slightly greater oxygen saturation was found with only 3.4 degrees C elevation in temperature. During the latter treatment considerable perspiration developed, while with the 6.5 degrees C rise in tem-

9. Goldschmidt, S., and Light, A. B. The Effect of Local Temperature upon the Peripheral Circulation and Metabolism of the Tissues as Revealed by the Gaseous Content of the Venous Blood. *Am. J. Physiol.* 73: 146-172 (June) 1923.

perature the limbs remained perfectly dry. The difference between the two temperature readings may be some indication of the effect of perspiration on the peripheral temperatures.

In another control case, more than 100 per cent increase in oxygen content occurred with only 2.4 degrees C rise in temperatures. Instead of the inverse change the carbon dioxide content was increased. The same condition of increase in both oxygen and carbon dioxide was found also in three patients suffering with severe peripheral circulatory disease. This was due probably to accumulation of carbon dioxide in the tissues as a result of the disease. In five cases of this series the venous blood from the heated arms showed a similar disagreement, one of which occurred both in the arms and in the legs. This was a case of severe arteriosclerotic disease which subsequently, with inten-

decline in oxygen content must signify greater oxygen consumption due to tissue metabolism than was compensated for by any increased flow of blood.

Alternating pressure treatments alone produced changes in the oxygen-carbon dioxide ratio and the skin temperatures, which for the most part indicated increased tissue metabolism (table 2). In this series eight of the eleven cases presented elevated skin temperatures, five of which were under 1 degree C. The highest reading, 2.7 degrees C, occurred in a patient who had received 136 hours of treatment. Except in one control and the patients with Buerger's disease all showed reduction in the oxygen content of the blood following treatment. These results do not substantiate the contention that increased circulation follows pressure treatments. At least in the presence of severe circulatory deficiency the results indicate increased

sive treatment, had the normal relation in oxygen-carbon dioxide content.

With marked organic occlusion of the peripheral arteries, little change in oxygen-carbon dioxide content followed the initial one hour treatment. Still, almost all the extremities showed some increase in skin temperature. After intensive treatment the changes in oxygen-carbon dioxide content indicated a marked increased rate of flow, but this was not accompanied by any greater increase in skin temperature. In two cases decreased skin temperatures occurred despite oxygen-carbon dioxide changes, indicating markedly increased flow of blood. Both patients had considerable perspiration. It is apparent that skin temperature changes are not entirely reliable and, undoubtedly, perspiration interferes with accurate temperature readings. We believe that higher temperatures would have been recorded if perspiration had not occurred.

Decreased oxygen and increased carbon dioxide content was found in five cases, four of which presented elevated skin temperatures. In one case there was a decline of 2 degrees C, but the entire group perspired. With all patients perspiring and the majority (four out of five) having a rise in skin temperatures, the

utilization of oxygen by the tissues. The minor temperature elevations might be due therefore to the increased metabolism of the tissues treated.

Direct heat was applied to the lower extremities of five patients for its effect on the local circulation (table 3). In four cases there was increased oxygen and decreased carbon dioxide content of the venous blood and increased skin temperature readings of the toes from 1.2 to 2.2 degrees C. This is completely in accord with our interpretation of increased circulation. One patient with the reverse condition (table 7) is suffering with severe diabetic arteriosclerotic disease of the left leg.

Heat to the arms for reflex vasodilatation in the legs was studied on five patients (table 4). In this series four showed increased skin temperature changes of from 1 to 4.6 degrees C. The same patient who had a decline of 1.6 degrees C with direct heat had a 0.6 degree C decline with reflex vasodilatation. Only one patient had a reduction in the oxygen content and increase in the carbon dioxide. With 3.3 degrees C elevation in skin temperatures there must have been greater utilization of oxygen than was supplied by an increase in circulation.

Judging from the results of gas analyses of the venous blood and temperature readings, reflex heat is more effective in producing increased circulation than direct heat or pressure treatments. However, pressure treatments produced more significant evidence of increased utilization of oxygen by the tissues. Reflex heat and pressure treatments combined produced not only the highest elevations in skin temperature but also the most marked changes in the oxygen-carbon dioxide content of the venous blood.

Total body metabolism tests were made on twenty-four patients before and after our routine form of pressure treatments (table 8). Slight changes in total oxygen consumption and total carbon dioxide elimination had no apparent relation to the changes in skin temperature readings. Sixteen showed increased oxygen consumption and eight decreased. Because of the normal factors of error in metabolic determinations, these results do not appear significant. However, in view of the general body relaxation and rest (frequently sleep and relief from pain) during the treatments a lowered oxygen absorption rate could have been expected. The elevated skin temperatures, at least in part, could be the result of increased local tissue metabolism. There is no increase in mouth temperature.

COMMENT

Increased circulation of blood does not explain the clinical improvement that follows treatment of peripheral circulatory diseases with alternating positive and negative pressure. Other therapeutic measures, more effective in increasing peripheral circulation, as determined by elevated skin temperatures, are of definitely less clinical value. On the other hand, Barker,¹⁰ Schwartzman,¹¹ Frey,¹² and others have used tissue extracts with successful clinical results in spite of the absence of demonstrable increased circulation. Nevertheless Landis,¹ Herrmann,¹ Allen and Brown,¹³ de Takats,¹⁴ Conway,¹⁵ and Shipley and Yeager¹⁶ attribute the beneficial results of pressure treatments to increased circulation of blood. Herrmann¹ recently has mentioned that some value of positive and negative pressure treatments might be in improved local tissue metabolism. We believe there is little doubt that improving the circulation in the extremities, especially in the presence of circulatory disturbances, simultaneously influences the oxygen consumption of the tissues. However, our results seem to indicate that alternating pressure treatments primarily effect the oxygen-carbon dioxide exchange in the tissues regardless of whether or not increased circulation occurred.

Barcroft¹⁷ distinguishes between anoxia, which means oxygen want, and anoxemia, oxygen deficit in the blood. In the large majority of patients with peripheral circulatory disease there is no oxygen deficit in the arterial blood. However, at least in the most severe

cases of circulatory deficiency the tissues seem to be unable to utilize the available oxygen supply—an anoxia. According to Peters and van Slyke,¹⁸ the physiologic effect of anoxia is "directly attributable to diminished oxygen tension in the tissues."

Oxygen is carried in the blood by the hemoglobin, an efficient arrangement for increasing the oxygen carrying capacity of the blood. The gaseous exchange in the lungs and tissues is on a physical basis, passing from the regions of higher concentration to those of lower. This is in accordance with the laws of diffusing gases. Elimination of carbon dioxide from the tissues and blood is by the same process. The oxygen in the air which is brought in contact with the blood in the alveoli passes from the place of higher to lower tension. In this way the blood absorbs oxygen to the extent, normally, of 20.9 volumes per cent. From the blood the oxygen then passes to the tissues because of lower oxygen tension. Similarly the carbon dioxide accumulating in the tissues is under greater pressure than is that in the blood. Accordingly the blood absorbs carbon dioxide and carries it to the lungs, where it is expelled because of the still lessened carbon dioxide pressure in the air.

The changes in environmental pressures as a result of pressure treatments seem to be less likely to increase the flow of blood, especially in organic blood vessel disease, than it is to change the oxygen-carbon dioxide tension in the tissues. These changes in tension would effect the diffusion of oxygen from the blood to the tissues and carbon dioxide from the tissues to the blood. In other words, improved local tissue metabolism follows such pressure changes. Less elevation in skin temperatures is produced by this oxidation process than by increasing the flow of blood. The results of this investigation indicate that this actually takes place during treatments with alternating positive and negative pressure.

Since most peripheral circulatory diseases have some vasoconstriction element,¹⁹ heat applied to the arms is an efficient means of producing reflexly maximum vasodilatation in the lower extremities. Therefore the additional elevation in skin temperatures which follow combined pressure treatment and reflex heat indicates that the therapeutic effect of pressure treatments is not due to vasodilatation. Both Herrmann and Landis have suggested recently that some form of heat be used in conjunction with pressure treatments. The results herewith reported provide an adequate explanation for the superiority of the combined form of treatment. Reflex heat produces maximum vasodilatation with an increased circulation, while pressure treatments increase tissue metabolism. In our experience this procedure is the most effective means of relieving the pathologic changes in the tissues due to deficient circulation.

The respiratory function of the skin itself may be an important factor in the clinical improvement that follows pressure treatments. The cutaneous surface is capable of absorbing oxygen from the air and eliminating carbon dioxide. Shaw and Messer²⁰ inferred from the results of their investigation that gases continually pass in and out of the blood by diffusion through the skin. Under ordinary conditions the average amount

of oxygen absorbed by the skin corresponds to one one-hundredth of the amount absorbed by the lungs²¹ The amount of oxygen that can be absorbed was found to vary according to the temperature and concentration of the gas With a constant oxygen tension in the blood, the rate of oxygen absorbed from the air will vary directly with its oxygen tension Consequently the alternating pressure treatments in changing the oxygen-carbon dioxide tension in the air should influence the respiratory function of the skin The few irregularities in our results in the oxygen-carbon dioxide content of the blood following pressure treatments might be due to this factor

Neurocirculatory disturbances are frequently associated with atrophic arthritis Local treatment for arthritis is directed usually to increasing the circulation For the same reason Rowntree and Adson²² perform sympathectomies with some encouraging improvement in the arthritic condition The increased circulation that follows this surgical procedure relieves the neurocirculatory symptoms, but White²³ reports that in his experience there is little change in the course of the arthritis

The fact that our routine procedure of reflex vasodilation and pressure treatments has given such good clinical results in peripheral circulatory diseases suggested its use in atrophic arthritis associated with neurocirculatory disturbances The increased circulation would relieve the symptoms due to the circulatory deficiency, and the improved local tissue metabolism as a direct result of the pressure treatments might be beneficial to the arthritis Accordingly Dr E E Irons and Dr E M Barton selected a group of cases which most closely met the requirements of Rowntree and Adson²⁴ for sympathectomies Their clinical results will be reported separately

SUMMARY

The purpose of therapeutic procedures for peripheral circulatory disease is to promote increased circulation of blood in the extremities These procedures include hot applications, contrast baths, diathermy, baking, exercises, massage, nonspecific vaccines and, most recently, alternating positive and negative pressure Although these measures are extensively used, little definite information is available as to their relative value Increased skin temperature readings are of some help in estimating the extent of improved circulation This is particularly so following sympathectomy in selected cases of vasospastic disease In the absence of definite elevations in skin temperatures, clinical observations alone have been relied on in determining the success of the therapeutic measures The results of this investigation indicate that the beneficial effects of pressure treatments is on a physiologic basis of increased tissue metabolism

The addition of reflex heat to the pressure treatments has given the best clinical results The heat produces increased blood flow as a result of maximum vasodilation and the pressure treatments increase the exchange of oxygen-carbon dioxide in the tissues Since the natural course of most peripheral arterial diseases is

progressive, no estimate can be made as to the permanent effect of the pressure treatments The improvement in peripheral circulation must be kept in advance of the disease process Gas analyses for the oxygen-carbon dioxide exchange in the tissues and peripheral temperature readings are of value in determining how frequent and how intensive the treatments should be

Except for the controls and the patients with arthritic neurocirculatory disease, the other patients had severe organic occlusive disease In some of the latter cases, preliminary nerve block²⁵ was done with procaine hydrochloride to establish the fact that our routine combined form of treatment could produce greater elevation in skin temperatures than occurred with maximum vasodilatation Although the results herewith reported are concerned with one hour treatments, subsequent periodic determinations can be accepted as the cumulative effect of the treatments As an index to the cumulative effect, the total number of hour treatments is given in the tables

The respiratory function of the skin may be an important factor in the success of pressure treatments It is interesting that the cutaneous surface is capable of absorbing oxygen from the air and eliminating carbon dioxide With organic arterial occlusion the skin is usually dry and atrophic Reid²⁶ has emphasized the need of proper care in cleansing and greasing the skin Keeping the skin soft and pliable probably aids the cutaneous surface in absorbing oxygen from the air and eliminating carbon dioxide into the air With this in mind the care of the skin should be an important part of the routine care of the extremities in peripheral circulatory disease

Although the results of the total metabolism tests indicate some increase in oxygen consumption following our routine form of treatment, they are used only as possible corroborative evidence for our other observations The factors of error in determining metabolic rates are too great to permit accepting these metabolic readings alone as conclusive evidence of increased oxygen consumption following treatments with alternating positive and negative pressure

CONCLUSIONS

Correlating the results of gas analyses for the oxygen-carbon dioxide content in the venous blood of the extremities before and after positive and negative pressure treatments with the elevations in skin temperatures has provided a physiologic basis for treating peripheral circulatory diseases with alternating changes in environmental pressures

Alternating positive and negative pressure treatments primarily effect the oxygen-carbon dioxide exchange in the tissues This oxidation process may account for the increased skin temperatures There is little evidence that circulation is increased, especially in the presence of organic occlusive disease

Vasodilatation as a result of direct heat or reflex heat is more effective in increasing peripheral circulation but apparently has little effect in augmenting oxygen-carbon dioxide exchange in the tissues The increased circulation merely increases the adequate oxygen supply that is still available

Combining reflex vasodilatation with pressure treatments, our routine procedure is of distinctly more

clinical value than either measure alone. The reflex vasodilatation produces maximum increase in circulation and the pressure treatments augment local tissue metabolism. The resulting greater utilization of increased oxygen supply seems to be the basis for the superiority of this form of combined treatment.

The permanence of the improved circulation and local tissue metabolism cannot be determined because of the natural progress of most peripheral circulatory diseases. It is advisable to keep the improvement in circulation in advance of the disease process.

THE MASSIVE BONE GRAFT IN UNUNITED FRACTURES

MELVIN S. HENDERSON, M.D.

ROCHESTER, MINN.

The problem of the ununited fracture is one that I brought before the Section on Orthopedic Surgery in 1921, reporting 247 ununited fractures, and again in 1923, discussing the treatment of 220 patients who had fractures in a fixed state of nonunion, both of these series of cases were encountered at the Mayo Clinic. Basing this paper on material encountered in the same institution, I venture to discuss again the treatment of ununited fractures and am reporting the results in treatment of 336 traced patients of a total of 374 who have been operated on since my last report. My reason for this presentation is that at the clinic with increased experience we have evolved a comparatively simple technic that gives a higher percentage of good results than we have heretofore obtained. Experience has taught us that the larger the graft, the better the chances of success. We have termed this type of graft the "massive graft." Campbell uses the same type of graft and calls it the "onlay graft." It might well be designated as the "massive, onlay autogenous graft." Some of our patients had more than one ununited fracture, thus the 374 patients had a total of 413 ununited fractures. There were 288 males and eighty-six females, whose average age was 33½ years.

The order of frequency with which the various bones were sites of ununited fractures was as follows: 1. The tibia was involved in 132 instances and the site of fracture was the upper third in twelve, the middle third in sixty-five and the lower third in fifty-five. 2. The radius was involved in seventy-nine instances, the fracture was in the upper third in three, in the middle third in thirty-two and in the lower third in forty-four. 3. The involved bone was the humerus in seventy-four instances, the site of fracture was the upper third in nine, the middle third in thirty-three and the lower third in thirty-two. 4. The femur was involved in sixty-eight instances and the site of fracture was the neck in thirty-seven, the upper third in seven, the middle third in sixteen, and the lower third in eight. 5. Fifty of the ununited fractures affected the ulna, the site of fracture was the upper third in thirteen instances, the middle third in twenty-four and the lower third in thirteen. The ununited fractures were of other bones in ten instances.

Two hundred and fifty-four of the total number of patients had initially simple fractures and 120 had

compound fractures, but 215 of the patients had fractures associated with severe confusing, twisting or crushing types of accidents, which emphasizes the fact that a large percentage of ununited fractures are associated with severe injury. Two hundred and four patients of the total number of 374 had been operated on previous to their visits to the clinic, some three or four times or more, and in operations on 100 of the patients some form of metal, such as plates, bands or wires, had been used for internal fixation. Fifty-five patients had been submitted to autogenous bone grafting operations elsewhere but roentgenograms disclosed that in the majority of these cases the graft had been very small and did not approach fulfillment of the massive graft. A considerable number of these grafts had been inserted in the presence of a draining sinus.

As has been stated, in some cases we treated more than one ununited fracture by transplantation of bone and in a few cases we inserted second bone grafts because of failure of the first. Among the 336 traced patients, 367 fractures were subjected to bone grafting operations. Calculating the results on the basis of traced patients, there were fifty-two failures and 284 successful results, or 84.5 per cent of the patients obtained bony union. Calculated on a basis of the number of fractures treated, the percentage of success is practically the same, the fractures of both bones of the forearms were those which chiefly increased the number of operations over the number of patients. The results in the traced cases, according to the bones fractured, were as follows: tibia, 118 with ninety-six bony unions, or 81 per cent, the radius alone, forty-six with forty-one bony unions, or 89 per cent, the humerus, sixty-three with fifty-five bony unions, or 87 per cent, the femoral neck (intracapsular), thirty-three with twenty-five bony unions, or 76 per cent, the femoral shaft, twenty-five with twenty bony unions, or 80 per cent, the radius and ulna together, twenty-three with twenty bony unions, or 87 per cent, and the ulna alone, seventeen with fourteen bony unions, or 82 per cent. Obviously the twenty-three instances in which the radius and ulna both were sites of ununited fracture must be thought of as representing twice twenty-three bones if all bones fractured are to be counted in the total.

TYPES OF BONE GRAFT

The intramedullary graft must be mentioned but not for approval. It is still used occasionally, particularly for fractures of the shaft of the femur that are delayed in uniting, but it is not suitable for the typical case of nonunion. It is a foreign body in the medullary canal, has no physiologic action and provides only fair fixation.

The osteoperiosteal graft is perhaps best suited for use in treatment of children. Osteoperiosteal grafts give no support and we have not been satisfied with results from their use.

The inlay method of Albee is characterized by precision and accuracy in fitting the bone graft (fig. 1a). Its most useful field is in treatment of fractures of the tibia where exposure is easy, but in dealing with small bones such as the radius and ulna and with the deeply placed femur only a few surgeons are capable of the meticulous technic necessary.

The massive graft which is applied and firmly held to a broad well prepared area on each fragment has been in our hands, the most successful (fig. 1b).

One distinctive advantage of the inlay and the massive onlay graft is that they provide good fixation

However, because considerable absorption takes place before any bone graft is vascularized and revitalized, a period of weakness develops. Therefore adequate external fixation, preferably by plaster casts, must be provided until union has become complete. Disregard of this leads to undue strain on the graft and in the period of weakness it will generally fracture.

The larger the graft the more strength it has in this period of weakness, during which revitalization takes place. Thus experience has taught that, other things being equal, the larger the graft, the better the chance for success. It is because of this fact that I wish to stress the term "massive" and to urge that it be retained in speaking of this type of bone graft, thus emphasizing the fact that bone grafts should be as large as possible.

A discussion of the physiology of repair of bone is not within the scope of this paper. The part played by the periosteum has been written about extensively and, although the periosteum should be retained if possible, clinically we have never been convinced that it was of any great importance. It is well to take the bone graft from as near the epiphyseal region as possible, for it is in that area that the bone cells are the most active physiologically and, as I shall later stress in discussing the technic, the small pieces of spongy bone obtainable close to the epiphyseal line are very important, a fact not generally appreciated.

SELECTION OF CASES

One of the outstanding causes of failure is post-operative infection. The percentage of cases in which infection follows operation, if infection is not previously present and if the field of operation is free of scar tissue, is no higher than in other types of surgery. A good number of the total number of patients, 204, as has been said, had been operated on before coming to the clinic and they had varying degrees of scar tissue. In eighty-one of the traced cases infection had taken place, either at the time of accident or at the operation performed before the patients came under our care and, although healing had taken place by the time of our operation, in twenty-two cases, or 27 per cent of cases in which infection once had been present, infection developed after our operation. Of 255 cases in which infection had not taken place, either at the time of accident or at previous operations, in thirty, or 11 per cent, infection developed. This percentage of infection may be higher than that encountered in the usual run of clean surgical cases, but it must be remembered that many of these patients had extensive scarring, both in the skin and in the deeper structures, attributable either to the injury or to previous operations. It was necessary to expose the fragments through this nonvascular scar tissue and the trauma necessarily incident to the operation produced a field that easily became infected. Even if frank infection does not develop after operation, scar tissue of the fascial planes or of the skin may undergo necrosis and, as these tissues break down, the semiliquid, degenerating mass occasionally becomes infected from the blood stream. We have had no deaths from infection nor have we been forced to amputate for infection in any of this series of cases. There was only one death and that was attributable to a cerebral embolus finding its way through a patent foramen ovale in the heart of a woman who had been subjected to a bone grafting operation for ununited fracture of the neck of the femur. Death occurred on the fourth day after operation.

Sinuses must be healed and all redness and swelling must have disappeared for many months before repair of an ununited fracture is attempted. We have come to insist on at least six months having elapsed between the disappearance of these signs and the time selected for operation. Infection occurring in a wound after transplantation of bone usually means failure.

MASSIVE GRAFT

Our percentage of successful bone grafts has increased, I believe because we have become more judicious than we formerly were in selection of the time to operate, because we use the massive graft and because we have improved the actual technic of placing the graft.

The patient's general health, of course, should be investigated, but patients who have ununited fractures, taken as a group, are of the healthy, robust type. The cause of failure of a fracture to unite is a local one in most cases, but in this paper I cannot discuss this

Fig 1—*a* inlay graft held by beef bone screws *b* massive graft held by beef bone screws. Note greater amount of bone also multiple spongy bone transplants at line of fracture.

interesting phase of the subject. Syphilis, in our experience, has not been a factor. If the patient had syphilis we treated for this disease until the blood was negative and then proceeded with our surgical work.

PREPARATION OF FRACTURE SITE

The extremity should be shaved if necessary and any of the recognized ways of rendering the skin sterile may be used. A tourniquet should be used unless its use is contraindicated for some reason.

TECHNIC

The incision should be adequate to allow exposure of the fracture and sufficient of the fragments so that the massive graft can be applied. The skin should be draped carefully with towels.

Dissection down to the bone should be carried out with the least possible trauma and without unnecessary stripping back of the periosteum and tissues surrounding the bone. This is extremely important if the fracture has been compound or if previous operations

have been performed, for rough handling of scar tissue may lead to gangrene and slough. The ends of bone should be exposed, the fibrous tissue removed from between them, the rounded ends reshaped, the medullary cavities opened and the ends of the bones fitted together, even at the expense of shortening. Shortening of a leg by 1 inch (2.5 cm) can be easily compensated for.

The cortices of the fragments where the graft is to be applied should be freshened by aid of the chisel. We have come to believe that the use of a sharp chisel is preferable to the saw for the slightly irregular surface produced by the chisel is more conducive to a take of the graft than is the smooth ground surface left by the circular saw. The outer layer of the cortex should

Fig. 2—*a* removal of massive reversible graft for ununited fracture of tibia by aid of chisel and drill holes. *b* removal of spongy epiphyseal transplants from upper end of bone. *c* cross section showing large graft obtainable from tibia and *d* reversible massive graft in position with multiple spongy graft about site of fracture.

be chiseled away until the deeper, vascular tissue bleeds. This preparation should extend well beyond the line of fracture into the healthy bone of each fragment, the distance varying with the bone involved. For the humerus the graft should be at least 10 cm long and slightly longer for the femur. While bone for the graft is being obtained the wound should be filled with a saline pack and the skin drawn snugly together with skin clips to control oozing, for the tourniquet should be removed at this stage.

Removal of Bone Graft—If a second surgical team is available to remove bone for the graft, the time will be materially shortened. The graft should be removed from the flat internal surface of the tibia as near the upper epiphyseal region as possible. The graft can be taken out with a motor saw or by drilling multiple holes and then chiseling between them (fig. 2 *a*). In

operating on an adult it is possible, with a good sized curet, to remove spongy bone contiguous to the upper epiphyseal line (fig. 2 *b*). These scrapings are of the greatest aid and should be kept warm and moist in a saline pack. The rough medullary portion of the bone graft is removed with bone biters until the deep cortical layer is reached. This material is saved, along with the other scrapings of spongy bone. The wound in the leg should be closed immediately and bandaged.

Application of Massive Graft—The wound at the site of fracture is opened, the fragments are held firmly together, and the flattened, medullary side of the bone graft is placed against the prepared areas on the cortices and held firmly in this position with bone holders. A drill is then put through the bone graft, through the proximal cortex, across the medullary cavity and through the opposite cortex. Then a tap of the same size is put in to steady the bone graft, and this process is repeated so that the four taps are left protruding in each fragment. This steadies the fragments and the bone graft, and the surgeon can then tell whether the position is satisfactory. If it is, one tap is removed and a beef bone screw of corresponding size is inserted. This is repeated for each drill hole, securely holding the fragments in position. The large tops of the screws are bitten off with a bone biter.

The next step is almost as important as the use of the graft. The bone graft steadies the fragments, it is true, but the scrapings that are saved to be packed around the site of fracture and along the margins of contact of the bone graft with the fragments, near the line of fracture, furnish great physiologic stimulation and help in causing the fragments and graft to unite rapidly. This insures a large amount of spongy bone near the fractured ends, which are sluggish physiologically and need this stimulation. The wound is then closed and a plaster-of-paris cast is applied, to be worn until union is complete. If there is considerable oozing and soiling of the cast, it can be removed at the end of three or four weeks and a new one applied.

SUMMARY

A review of the records of 374 patients who had ununited fractures discloses that 413 fractures were treated. Some patients had more than one ununited fracture, for example, both radius and ulna.

Three hundred and thirty-six patients were observed long enough for us to be certain as to the result. Two hundred and eighty-four, or 84.5 per cent, obtained bony union. Among the traced patients were 367 fractures which were subjected to bone grafting, and the results when calculated according to the number of operations was practically the same as when reckoned according to the number of patients.

The "massive" graft the same type as that which Campbell calls the "onlay graft," is our choice. The secure fixation with accurate fit and the packing about the site of fracture of scrapings of spongy bone obtained from near the epiphyseal line are necessary steps in the operation.

ABSTRACT OF DISCUSSION

DR. OSCAR L. MILLER, Charlotte, N. C. Massive bone transplants or implants are primarily indicated for bridging defects in long bone or for mobilization of joints. Defects in bone may be seen as extensive shaft bone substance or neglect from nonunion at some point along the shaft. While the massive bone graft operation is carried out for the purpose of stimu-

1 We use either a standard #32 or 10/32 Standard American Machine screw tap according to the size of the drill used.

lating new bone growth, such a graft should generally be so implanted as to act at the same time as an internal fixation splint to the affected parts. In spite of how secure, though, the internal fixation of the implant may appear to be, further external fixation measures are indicated. The best types of bone graft appear to be the massive onlay grafts in the hands of surgeons equipped to make up the autogenous elements necessary, and the wedge-in implant. My experience has been largely with the latter, where long bone defects have been encountered. When using the wedge-in bone grafts, one may carry to the defect quite a lot of medullary bone along with the cortical mass, and also give positive pressure between the defective bony ends. There appear to be indications for two main types of massive grafts, the onlay and the wedge-in, and both should be transplanted with a view to bone regeneration and, at least temporarily, internal splinting for fixation. I have had some experience with failure in using massive bone grafts to bridge defects of the tibia, particularly when repeated operations have been carried out through the tissues of the shin. Twice I have been able to succeed with such a graft by exposing the posterior surface of the tibia and transplanting to that aspect of the bone where both the soft and bone tissues had not been traumatized.

DR. FREMONT A. CHANDLER, Chicago. The large series of cases that Dr. Henderson has had is remarkable, when one thinks of the traumatic surgery that has been done in these cases and that more than 200 of the patients had been operated on from one to seven or eight times before he received them for treatment. It shows the failure of much of our bone surgery. When placed in proper hands, the results may be satisfactory after so many failures. It is interesting also to note the high percentage of nonunions associated with foreign material fixation, especially the metals, plates and wires. In view of the extensive surgery done previously in these cases, with the scar tissue harboring potential infection his percentage of 24 per cent infections seems low. One point that has not been touched on is the function of the bone graft. The function of bone is the withstanding of pressure. A bone transplanted into soft muscular tissue will absorb, whereas bone subjected to some end pressure will survive. So, in placing a bone graft, I like to have some end strain, but, as Dr. Henderson has mentioned, I try to avoid the torsion and cross strains that would result in fracture. Another point in his paper that was illuminating is the high percentage of nonunions in the upper third of the tibia rather than in the ordinarily more popular area of the lower third. I think the general conception is that the nonunions are more frequent in the lower third. His paper emphasizes the upper third rather than the lower third. This presentation also completes the symposium on fractures of the neck of the femur, and I see that a large number of the nonunions that were being worried about two days ago may be solidified by massive bone grafts.

DR. W. K. WEST, Oklahoma City. My experience in the use of massive autogenous bone grafts has been limited to the modified Campbell technic which is slightly different from the method described by Dr. Henderson. The principal difference is that the onlay graft is held in position by autogenous bone pegs. Anatomically, the most difficult area for successful bone grafts is the upper humerus and upper radius. Onlay grafts are best suited to the humerus, ulna and radius. In the tibia I prefer the inlay and in the femur the intramedullary autogenous bone peg. Where metal fixation has been previously attempted, such as the use of Lane plates, Parham bands or wire, it is better to remove the foreign bodies as a preliminary operation to the massive bone grafting. Great care is necessary in obtaining mechanical efficiency in cases in which there is marked bone atrophy. In those cases of fracture of the upper humerus it is best to drive the upper end of the graft into the cancellous portion of the head, as it is impossible to obtain fixation in atrophic cancellous bone. This operation calls for two teams experienced in bone surgery. Old compound fractures must not be operated on sooner than one year after the cessation of drainage. Adequate external fixation is most essential and should be maintained for many weeks until such a time as the roentgenogram shows adequate bony union.

DR. MELVIN S. HENDERSON, Rochester, Minn. I didn't show lantern slides of cases that I had operated on for the reason that I wanted to confine the discussion to the essential fundamentals of technic. I would like to emphasize again that the

bone grafts should be large and that the fragments should be well prepared and freshened for the reception of the bone graft. The graft should be smoothed down on the medullary surface so that the deep layer of cancellous bone is exposed, and it should fit snugly to the fragments. The grafts should then be held firmly in place either by beef-bone screws or by autogenous pegs, if the fragments are very osteoporotic. Parham bands may be used. Firm fixation must be obtained. Around the fracture line and along the edges of contact of the graft to the fragments little pieces of spongy bone, secured from near the epiphyseal line, should be carefully packed. These small grafts are very important and the results have been more uniformly good since they have been used. In this mechanical age I think that a motorized circular saw is necessary to secure a bone graft. In one of the illustrations I showed a method of outlining the graft with multiple drill holes, a chisel being used to separate the graft between the drill holes. It can be done very readily if a thin bladed chisel is used and if care in chiseling is exercised. The transplant so removed is rough on the edges, which is really preferable to the more smooth even almost polished surface that follows the use of the circular saw, for it permits more readily revascularization of the transplant.

SIGNIFICANCE OF AN EPIDEMIC OF DENGUE

T. H. D. GRIFFITTS, M.D., D.R.P.H.
Surgeon, United States Public Health Service
AND
HENRY HANSON, M.D.
JACKSONVILLE, FLA.

Dengue, "breakbone fever" or "dandy fever" is an acute, febrile disease due to a filtrable virus which is constant in the peripheral circulation during the febrile stage. The disease is endemic in many tropical countries, and many explosive epidemics have occurred in subtropical and temperate climates.

Dengue is transmitted naturally by only one species of mosquitoes, *Aedes aegypti*, in the United States (so far as now known), while in the Philippines, in addition to *Aedes aegypti*, another species of *Aedes*, *albopictus*, has been shown to be infectable. Ashburn and Craig¹ demonstrated in 1907 that a virus in the circulating blood was the causative agent, although they apparently were in error in ascribing transmission of the disease to *Culex quinquefasciatus*, as was later proved by the studies made by Cleland, Bradley and McDonald² in 1916, Chandler and Rice in 1923 and Siler, Hall and Hitchens³ in 1925. Simmons, St. John and Reynolds,⁴ working in the Philippines, found that for an interval of at least nine days after feeding on a dengue patient, *Aedes aegypti* was not capable of transmitting the disease (extrinsic incubation period) but was infective after about twelve days following the ingestion of the blood from the patient. Once infective, *Aedes aegypti* remains so the remainder of its life, provided the atmospheric temperature continues favorable. It has been demonstrated by Blanc and Commopetras that with atmospheric temperature below 18 C (64.4 F) the virus in mosquitoes becomes non-infective. This accounts in a large part, perhaps, for the cessation of violent epidemics on the approach of

winter. However, *Aedes aegypti* is essentially a day biter, and preferring to remain indoors, as this house mosquito does, outdoor temperature is not a fair indicator of its ability to continue to administer infecting bites.

We have mentioned the fact that, in order to become infected, *Aedes aegypti* must secure blood from the dengue patient during the first forty-eight hours of the initial fever and that there is an extrinsic incubation period (in the mosquito) of about twelve days, then there is an intrinsic incubation period (in man) of from four to ten days. In all these characteristics and in the principal mosquito vector, namely, *Aedes aegypti*, the epidemiology is essentially identical with that of yellow fever, although unlike yellow fever in that ordinary laboratory animals have not yet been proved susceptible to dengue virus infection.

As to immunity, all endeavors at the establishment of cross immunity between yellow fever and dengue have proved negative. The immunity produced by an attack of yellow fever is practically absolute, while an attack of dengue produces a very definite immunity lasting only for a few years. It may be assumed that in a period of from five to ten years' freedom from dengue a given urban population in infectable territory is again susceptible to this disease. To illustrate, in the epidemic of dengue at Galveston, Texas, in 1917 it was estimated that 50 per cent of the population suffered attacks. Only five years later (1922) another epidemic occurred in which it was estimated that 60 per cent of the city's inhabitants were attacked.

The first recorded epidemics of dengue occurred at Cairo, Egypt, and Batavia, Java, in 1779, and in Philadelphia in 1780 (described by Benjamin Rush in 1818). Since that time this disease has ever brought to mind its striking similarity to yellow fever. Long before the transmitting agent of yellow fever (the mosquito *Aedes aegypti*) was definitely known, physicians in various parts of tropical and temperate zones observed and recorded facts concerning the parallel epidemiology of the two diseases. Strangely enough, Linnaeus eighteen years before the recorded epidemic in Cairo had found in Egypt also and described the mosquito that is now known as *Aedes aegypti* and which is a vector—at least the most important vector—of both yellow fever and dengue. Epidemics have occurred at more or less lengthy intervals in various areas between parallels 32° 47' N and 23° 23' S, and even beyond these lines at times. In other words, during favorable seasons of warm and wet summer months with resulting heavy production of *Aedes aegypti*, plus the introduction of a first case or the importation of infected *Aedes aegypti*, limited epidemics have occurred in areas beyond its ordinary boundaries, e. g., Philadelphia, Constantinople, Athens and other points in Greece.

The rapidity with which dengue spreads in non-immune populations is probably exceeded only by influenza. The fact that in most epidemics of dengue there is a relatively large percentage of cases of mild type, many unrecognized, or not officially reported, lays the foundation for widespread mosquito infection. In any given epidemic, ambulatory patients are not only more exposed to bites of mosquitoes in daytime than the bedridden patients but in travel, although restricted, chance to infect mosquitoes over a wider area is increased. This is responsible then, for the greater rapidity of the spread of dengue than in the case of yellow fever. On the other hand the dreaded mortality from yellow fever incites greater activity in

preventive measures, such as prompt and accurate reporting of cases, greater care in protecting not only the sick but the well from mosquito bites, the employment and training of medical and sanitary personnel, and the expenditure of funds for epidemiologic investigations and vector control.

One frequently hears, even today, that dengue is only a painful disease of short duration, the patient "sick enough to die but doesn't." This is misleading. While recovery occurs in uncomplicated cases of dengue, the same may be said of many other diseases.

According to records, the city of Athens, Greece, had approximately 239,000 cases of dengue up to September 4, in the 1928 epidemic. This represented 75 per cent of the population of the city. The registered deaths from all causes in Athens for the month of August 1928 totaled 1,268, of which 413, or 32.6 per cent, "were certified as due to dengue." In Piræus, a city of 136,000 during the same month the registered deaths from all causes numbered 592, of which 176, or 29.7 per cent, "were caused by dengue."

In the average epidemic of yellow fever, about 10 per cent of the cases are fatal, the same as from typhoid. But in the days when diagnoses of yellow fever were made only when the patient had "black vomit" and died, it is no wonder yellow fever mortality seemed so appalling. As time goes on and research progresses, more and more is being learned about the epidemiology and the endemic characteristics of yellow fever and dengue. Through immunity tests for yellow fever in recent years developed by Sawyer and others, it is now known that yellow fever in its present endemic areas is not a deadly disease at this time but that the area of endemic prevalence is more widespread than was formerly considered.

The last pandemic of dengue in the Southern states occurred in 1922. The first cases were reported from Tampa, Fla. A relatively light prevalence in many communities was reported the following year, and in this country no epidemic followed for eleven years, when in 1934 dengue was reported (July 16) in Miami, Fla. The origin of the first case of dengue in the Miami epidemic is not known. It is assumed, of course, that either an infected person or an infective *Aedes aegypti* mosquito came into Miami by boat or by airplane from some endemic tropical center. Formerly dengue and yellow fever gained entrance to the United States by means of traffic across the Mexican border or by sailing vessel or steamship to Atlantic or Gulf ports. Today, with rapid airplane traffic between Cuba, the West Indies, South America, Central America and Mexico, an added danger exists. Yellow fever is now present on the Western hemisphere only in parts of Brazil, Colombia and Bolivia, so far as known, and, too, only in certain jungle areas.

The United States Public Health Service in 1931-1932 demonstrated the facility with which *Aedes aegypti* may be carried long distances in aircraft.⁵ Until this apparent menace was demonstrated and the newer knowledge concerning the extent of endemic yellow fever, particularly in Africa, with so-called jungle fever in Brazil, Bolivia and Colombia, with at least a dozen additional species of mosquitoes now known to be infectable with yellow fever virus and some species of monkeys readily susceptible, health officials the world over were hopeful of ultimate eradi-

⁵ Griffiths, T. H. D. and Griffiths, J. J. Mosquitoes Transported by Airplane. Pub. Health Rep. 46: 2775 (Nov. 20), 1931. Griffiths, T. H. D. Air Traffic in Relation to Public Health. Am. J. Trop. Med. 13: 283 (May) 1933.

cation of yellow fever. Today there is a feeling of concern lest our own infectable areas may again be invaded, and that Old World territory, where the vectors abound and where yellow fever has never before stalked, may experience widespread and devastating epidemics.⁶ One infective mosquito traveling in an airplane from the home of yellow fever (Africa) to India could be the spark to start the conflagration.

The facility with which dengue spread in Miami in the summer of 1934⁷ and thence into practically all parts of Florida and into parts of Georgia shows with what rapidity and certainty yellow fever, too, can still spread in our own country. Yellow fever was rather promptly brought under control by the application of anti-aegypti methods in our latest epidemic (1905), but it is erroneous to consider that this disease has been kept out by mosquito eradication in our Southern ports. Immunity against yellow fever in the Southern states or infectable territory today may be considered nil so far as danger of epidemic spread is concerned. It is doubtful whether 0.1 per cent of the population of infectable territory is protected by a previous attack of yellow fever. Consequently, we are still vulnerable to its devastation if once reintroduced.

When we were faced with the prevalence of dengue in Miami in July 1934 and the responsibility of preventing its spread, surveys in various cities, towns and villages reminded us of what we already knew—that in spite of our civic pride and detestation of mosquito bites there is still a complacency sufficient to tolerate an abundant production of *Aedes aegypti* throughout the habitat of this vector. In a period of two months dengue was reported in seventy municipalities in thirty-one counties in Florida and a few places (principally Savannah) in Georgia.

Practically every urban community in the South has its array of artificial containers, from flower vases to catch basins, cuspidors and discarded automobile tires, producing *Aedes aegypti*. For example, the city of Tampa in eight weeks reported finding 1,091,823 containers (potential mosquito "hatcheries"). Of these, larvae were found in 20,864, or approximately 2 per cent. This was an unusually dry season (average rainfall of 1½ inches a month for this period). It is interesting to note that in Miami for a like period only 56,598 potential breeding containers were reported, with 38,401, or 68 per cent, of the total actually breeding.

While we long assumed that only one mosquito (*Aedes aegypti*) transmitted yellow fever and dengue, it is now known that more than a dozen species in Africa and Brazil are susceptible to infection with yellow fever virus and that at least two species of *Aedes* (*aegypti* and *albopictus*) have been proved infectable with dengue in the Philippines (*Albopictus* has also been infected with yellow fever virus). It is worthy of note, at least, that the greater percentage of cases of dengue in the Florida epidemic occurred in coastal areas and that *Aedes taeniorhynchus* (the great salt marsh pest of Florida) has been proved susceptible to yellow fever virus in Brazil.

The senior author of this paper, in the course of malaria investigations over a period of more than twenty years, has had occasion to observe *Aedes aegypti* conditions in various parts of infectable territory. He

states without reservation that *Aedes aegypti* production is not now under control and never has been brought under reasonable control, except under stress of imminent danger of an epidemic of dengue or yellow fever. Only two factors have been concerned in our freedom from yellow fever during the past thirty-one years: (a) the constant vigilance in our national quarantine service and (b) the practical freedom from epidemics in Latin American countries to the south of us. How long the latter condition may prevail is mere conjecture.

ABSTRACT OF DISCUSSION

DR. V. H. BASSETT, Savannah, Ga. The authors have presented a message of great importance to Southern cities and especially to those on the Atlantic and Gulf coasts, because they have shown what we have long suspected, namely, that the fact that we have not had yellow fever was not due to our having conquered the insect vector but to the fact that neither the infected insect nor an infected human host has come into our territory as a source of virus. With the increased rapidity of transportation, especially by airplane, the danger of this is evident. The reason *Aedes aegypti* has not been controlled more carefully is largely due to the fact that it is not as annoying a mosquito as the other city mosquitoes. Another reason is that the adaptation of *Aedes aegypti* to man has been most exquisite in the delicacy of enabling it to breed in extremely small amounts of water and in the most unexpected places. No control that is not in itself searching will suffice. There have been epidemics in Savannah since early times: in 1913, when 20,000 people were sick in a population of about 70,000 people, in 1922, when 30,000 were involved in a population of about 85,000, and in 1934 when strenuous efforts were made for prevention after we found out what was going on in Florida and had fully 10,000 sick. The question of whether or not *Aedes aegypti* may not be altering its habitat and becoming more adapted to rural conditions is important. The question of the percentage of residences in which breeding was going on is important as a factor in determining the spreading of the disease. We made a test when the last epidemic began and found that breeding existed in 20 per cent of the yards. The most strenuous efforts were made to control this, and we were able to reduce that to only slightly below 10 per cent. I think we would have reduced the percentage more decidedly if I had been able to control breeding in roof gutters, not on open roofs, because mosquitoes will not breed there unless there is a great deal of shade. They breed in very little water, under leaves. It is considered that reduction of the breeding index of mosquitoes is effective if reduced below 5 per cent. There is a chance that one house where breeding exists infests four or five houses in the immediate neighborhood. I was sorry to hear what the authors had to say about *Aedes taeniorhynchus*, because if that mosquito proves to be a vector it is going to make it much more difficult for the cities located as is Savannah, near salt marshes, to prevent these epidemics. Fortunately, *Aedes sollicitans* is the more common marsh mosquito on our part of the coast and we do not find *Aedes taeniorhynchus* so often.

DR. T. H. D. GRIFFITTS, Savannah, Ga. We seem to have aroused considerable interest by mentioning *Aedes taeniorhynchus*. This mosquito has been proved susceptible to yellow fever virus. Nobody at present knows whether this species plays any part in the spread of dengue. I mention that because of the fact that the original yellow fever mosquito is also the outstanding violator in the matter of dengue. One should not overlook the possible significance of the frequently greater prevalence of dengue in coastal towns. The fact must be lost sight of that in case yellow fever should break out it might not be limited to one section of a city, as was often the case in former epidemics. Yellow fever used to be largely confined to the French quarter in New Orleans. With automobile transportation it is not unusual for an *Aedes aegypti* mosquito to get into a car parked by the side of the house overnight and be carried rapidly 5, 10 or 15 miles, even with the windows and windshield open, as I have demonstrated. So, while we have reduced certain reproduction areas or places by doing

away with above-ground cisterns, a prolific source of *Aedes aegypti* in former days methods of rapid transportation will cause rapid spread of either yellow fever or dengue in modern times, such as did not exist in the "horse and buggy days." I think that is true also in spreading *Aedes aegypti* to the smaller communities and even to farmhouses where they are occasionally found today, whereas this mosquito once was regarded as a city dweller.

HERNIOPLASTY IN PATIENTS PREVIOUSLY TREATED BY THE INJECTION METHOD

PRELIMINARY REPORT

GEORGE GORDON, M.D.

AND

ELIAS GORDON, M.D.

NEW YORK

The late Dr. J. Chalmers Da Costa,¹ referring to the work of Lannelongue, said

Lannelongue has for certain cases returned to the old injection plan, using a ten per cent solution of zinc chloride. The hernia is first reduced and is held up by an assistant who closes the internal ring with a finger and also holds the cord aside. Several injections of ten minims each are thrown into the region of the internal pillar and into the canal behind and outside of the cord. The surgeon must be careful that no zinc solution escapes into the subcutaneous tissue. The effect of the chloride of zinc is to cause the formation of quantities of fibrous tissue. It is scarcely to be expected that a cure so produced will be permanent in an adult, though it may be in a child.

As far as we know, Dr. Da Costa had never practiced the injection method, yet the foregoing statement revealed hope rather than doubt, curiosity rather than arrogance.

The rationale of the injection method, though perfectly reasonable and simple, was long rejected by the medical profession as unheard of insolence. When finally revived in recent years it had merited the following remarks in the British Medical Annual for 1931: "When we remember the scepticism with which the injection treatment of varicose veins was first received by the profession it would be unwise to refuse the slightest credence to these observations."

The injection method has its limitations. The fact that some authors consider it to be the method of choice in all reducible hernias of moderate size has prompted this preliminary report. The observations here presented indicate that sliding hernia is a direct contraindication to the injection treatment and that any attempts at the ambulant treatment of this condition may be fraught with disappointment and perhaps danger. Moreover the diagnosis of sliding hernia before operation is seldom possible and when it is ventured it is done so with a degree of uncertainty. Once the treatment of an undiagnosed sliding hernia has been initiated, the outcome will depend on the surgical judgment of the operator. If he possesses a fair amount of it together with the profits of personal experience, he will know when and why to stop injecting.

REPORT OF CASES

Five patients in our private practice had submitted to the operative repair of sliding hernia after a variable number of injections in the usual manner and spaced at biweekly intervals. The number of injections varied

from sixteen to thirty. The average lapse of time between the last injection and the operation was ten months. The patients were all men well over 40.

It was noted during the treatment that the canal was eventually obliterated and that the external ring was hardly palpable as such. No sooner was the truss removed, however, and the patient stood up erect, than a large hernial mass appeared in the canal, growing larger on straining and disappearing on lying down. During the various follow-up examinations it was found that the mass had regained a certain degree of mobility, increasing its excursion on coughing or straining. It was also remarked that the patients had a subjective feeling that the hernia was gone, although the swelling appeared in its customary place.

Under low spinal procaine hydrochloride anesthesia an incision was made in the inguinal region. The aponeurosis of the external oblique muscle was divided. An attempt to separate the aponeurotic sheath from the underlying muscle revealed dense fibro-aponeurotic tissue replacing the normal plane of cleavage. The conjoint tendon was next exposed and we observed a vast amount of newly formed cicatricial tissue extending in various directions. The numerous adhesions made it difficult to separate the mass from the posterior aspect of the external ring. The hernial mass was found to be composed of peritoneum forming the anterior wall. Closely adherent to it was a portion of the cecum. This viscus was separated from the sac, peritonealized and reduced. The redundant peritoneum forming the anterior wall of the sac was transfixed with a suture-ligature and cut away. The repair of the muscle wall was performed according to Bassini's method with transplantation of the cord. This patient was a man, aged 42.

Three other cases, originally diagnosed as right inguinal hernias, presented a sliding hernia of the cecum in two, and a portion of the bladder in the third. The fifth case, diagnosed as a left direct inguinal hernia, was found to present a sliding hernia of the sigmoid and omentum.

In order to explain the obvious failure of the injection treatment in these cases, a brief consideration of the subject of sliding hernia is submitted.

ETIOLOGY

1 In the embryonic group, one of the testes prior to its descent has grown to the wall of the cecum either with or without a special fold containing blood vessels. Having descended, the testicle drags the cecum along with it into the inguinal canal. According to Fleissig,² a sliding hernia may be due to the ptosis of the cecum from a congenitally low position. Although the mesentery of the ascending, descending and iliac portions of the colon normally adhere to the posterior abdominal wall and thus become lost, in some cases these primitive structures may persist. This may result in preternatural mobility of these parts of the large bowel and lead to hernia.

2 Mechanical causes such as constipation lifting heavy weights and other factors that influence intra-abdominal pressure may be responsible. The continuous filling and distention of the colon may result in the yielding of the layers of the mesentery, these layers separate, leaving the colon under its serous coat to emerge through the inguinal ring.

3 A simple hernia of the small intestine may imitate the condition, and after the sac is distended by the

¹ Dr. Costa, J. C. *Modern Surgery*, ed. 7 Philadelphia W. B. Saunders Company, 1918, p. 1139.

² Fleissig, quoted by Vergeron, *ibid.*

coils of the small intestine they pull after them the adjoining parietal peritoneum in the neighborhood of the internal inguinal ring. This peritoneum in turn pulls on the portion of the large bowel, which is partly peritonealized.

4 According to Tuffier³ and others, the cecum has two ligaments, the upper and the lower. When the upper ligament is weakened, the ascending colon drops below into the inguinal canal. The cecum either remains in place or follows the large intestine into the hernial sac.

5 Severe malnutrition, senile debility and a weakening of the abdominal wall may favor the development of sliding hernia. At this point it is interesting to note that a so-called relative hernia is a condition also associated with the debilitated state. According to Bickham,⁴ in this condition there is no absolute hernia existing in a sense that a part of the abdominal contents pass through and protrude from an opening in the abdominal wall. But there may be a marked bulging in asymmetrical or symmetrical fashion of a considerable area of the weakened abdominal wall between the umbilicus and the anterior superior iliac spine, caused by the transverse stretching of the aponeurosis of the external oblique sufficiently pronounced to constitute a relative hernia. It is needless to say that in the latter condition the injection treatment is contraindicated.

ANATOMIC CONSIDERATIONS

Only those parts of the large intestine can be involved in a sliding hernia which are not covered on all sides by peritoneum. Properly speaking, this would limit the sliding hernias to the involvement of the ascending or descending colon only. But in a larger sense adjoining loops of bowel and other viscera often participate in a general descent, especially the bladder, appendix and cecum. These organs are drawn down into the sac by the peritoneum investing them.

The posterior parietal peritoneum becomes detached from the underlying structure. It slides into the internal inguinal ring and carries with it the attached loop of large intestine. Next the intra-abdominal pressure forces the intestine into the point of least resistance, the internal ring. The ring now relaxes and the bowel travels down the canal, aided by its own weight.

Sliding hernias are classified as to the variety of sac into three groups:

- 1 Hernia with complete sac (intraperitoneal)
- 2 Hernia with incomplete sac (paraperitoneal)
- 3 Hernia without sac (extraperitoneal)

In the first group the mesentery is long and is found in the sac itself, and the mesentery appears consequently as the continuation of the sac. Complete sacs are generally present in congenital hernias and may contain the cecum, appendix, ascending colon or other viscera.

In the second group the mesentery is short, and the intestinal walls and mesentery are often adherent to the sac. This forms the largest proportion of cases. Here the intestine, which is covered by peritoneum only on its anterior and lateral surfaces, is directed into the sac. When the intestine reaches the sac its posterior nonperitonealized surface adheres to the floor of the inguinal canal or the internal ring.

Sacless hernias are infrequent and by some observers considered as prolapse of intestine through muscle.

DIAGNOSIS

The diagnosis of sliding hernia is usually made in the operating room. The surgeon should always be on his guard for hernia of the large intestine. Certain symptoms, however, may point to the possibility of a sliding hernia before the injection treatment is begun or surgery is employed, suspicion should be aroused in the presence of the following signs:

In all voluminous hernias

In all large hernias with a wide inguinal ring

When the mass is easily reduced in its medial aspect while the posterolateral aspect is reduced with difficulty

When the patient cannot tolerate a truss

In the presence of enteroptosis

In the presence of a doughy consistency on palpation

On palpating the hernial mass following reduction, one may occasionally distinguish the intestinal wall from the hernial sac.

Occasionally one may succeed in palpating the appendices epiploicae.

If the large intestine is distended with water, the hernial mass is increased and becomes firmer, followed by the disappearance of tympany on percussion.

Roentgen study may point to the possibility

COMMENTS

The reason why sliding hernia does not respond favorably to the injection treatment becomes evident when one studies the mechanism of this condition.

The nonperitonealized posterior portion of the large intestine becomes adherent to the internal ring and the floor of the inguinal canal.

This attachment becomes firmer as the hernia progresses. The apparent reduction of the mass in cases reported was really not true reduction. It resembled a rubber glove with its outer globular surface inverted by manipulation from convex to concave.

The actual lumen of the internal ring was not diminished by the treatment, and the upper portion of the inguinal canal could not be obliterated because of the attachment of the large bowel around the ring and in the canal.

To obtain satisfactory results as in simple hernias of the small intestine it would have been necessary to go through the layer of peritoneum that serves as the anterior wall of the incomplete sac. In this case the solution would have found its way into the peritoneal cavity or into the large bowel. The outcome would be obvious.

SUMMARY

1 In the presence of a sliding hernia and in the so-called relative hernia, the injection treatment is definitely contraindicated.

2 The diagnosis of sliding hernia being often impossible before operation, injections are frequently made with unsatisfactory results.

3 Sliding hernias occur in from 12 to 15 per cent of all hernias. They are usually right sided. They have a considerable tendency toward strangulation. They are often complicated by inflammatory processes within the hernial sac and occasionally by appendicitis. Baumgartner⁵ cites forty-four cases of strangulation out of 159 cases of sliding hernia, or 27.7 per cent. Vengerovski⁶ reports eight cases that were all right sided, involving the cecum and all presenting incom-

plete hernial sac. Of these eight cases three were strangulated and three were complicated by acute appendicitis within the hernial sac. The total number of cases in which injections were done by us was 386, so that in our experience the five reported cases of sliding hernia constituted approximately 1.3 per cent.

4. In the presence of a large hernia that resists all attempts at injection and recurs after a reasonable time has elapsed it is our practice to consider the possibility of a sliding hernia and resort to surgery.

5. Previous injections and the fibrous tissue proliferation resulting from the injections in no wise interfere with the operative procedure or the operative results.

35 East Sixty-Fourth Street

THE PSYCHONEUROTIC DEPRESSION

CHARLES H. KIMBERLY, M.D.

STOCKBRIDGE, MASS.

I have chosen the psychoneurotic depression as a subject that deserves more attention than it has been accorded in the current psychiatric literature. This discussion, and a recent paper given before the American College of Physicians at Detroit by Dr. Austen Fox, Riggs and Dr. Horace K. Richardson, may be considered as forerunners to a general and statistical survey of the problem presented by the psychoneuroses and their treatment at the Austen Riggs Foundation. Funds for this have been granted by the Markle Foundation and the study will be carried on by Dr. Gaylord Coon and Miss Alice Raymond.

Any inspection of the work at Stockbridge indicates that the psychoneuroses, instead of being distinct and separate entities, appear to be variants of the fundamental mental and physical dysfunction caused by the patient's underlying maladaptation to life. The variation in the expression of this maladjustment is probably determined by the basic elements in the patient's individuality. The stresses and strains in the environment are not causal and are of significance only as secondary and precipitating factors acting on this maladaptation.

Any adequate understanding of the neuroses must be based on a knowledge of the physical as well as the mental evolution, development and structure of man. The evolutionary significance is largely limited to the fact that more and more of the functions of existence have assumed automaticity, thereby releasing man's attention for the further improvement of the technic of living and the preparation of a more congenial environment. Any interference by the individual in this trend of development or any tendency to resist it results in maladaptation, since it either maintains him on or forces him to an inferior level of living that is inadequate for his successful relationships with his fellow man. Adaptation has anatomic and physiologic as well as psychologic significance and is based on the functional divisions of the central nervous system. The more recently acquired unit exerting a retarding or inhibitory influence on the more primitive. The anatomic level below the cerebrum is probably of greatest significance in this discussion, since incomplete subordination of the function of this level to the needs of the forebrain probably constitutes the functional or

anatomic foundation for the neuroses. Incomplete integration is seen in the amplification of the sense impressions, the increased conscious responses to emotions, the marked sympathetic manifestations and even the motor responses. Complete integration inhibits the violence of response from the lower level while making use of its dynamic potentialities.

The inner experiences of man are built on this foundation and we can further reconstruct our understanding of the development of the psychoneuroses by correlating the psychologic with the other processes of maturation whereby complete integration is attained. The infant represents roughly a conscious though subcortical mechanism, perceiving imperfectly, feeling violently and responding to these emotions by instinctive action. This is the starting point of human behavior, subsequent additions being determined not only by the stimulation of the physical and psychologic environment but also by the skill with which the child learns to develop the potentialities of the forebrain.

The child lives in one of the most complex interactions of individual and environment, namely, that of the parent-child relationship, wherein the oversolicitous parent in his response to parenthood reacts on a more or less primitive level where exaggeration of expression of love and attention tend to predominate. This, while favorable to the first stages of development, can become a contributing factor in the origin of the individual's maladaptation and subsequent neurosis.

The over-idealistic parent, with zealous intent but little intelligent restraint, may impress on the child distorted standards of behavior as patterns of normal adult reaction. No consideration is given to the fact that the child also responds primitively because of his incomplete development and therefore further distorts and elaborates these impressions to the point where he sets unattainable standards of behavior for himself which he assumes to be desirable measures of conduct and a necessary protection from the dreaded consequences of self-indulgence. Self-restraint, instead of objective behavior, becomes the means to his ideals. This represents a physiologically expensive mode of behavior. This may be called overmanagement of self, since autonomic functions continue to absorb the attention.

Often the child tries to modify the exhausting tension of this type of existence by seeking the psychologically tonic effect of approbation. If parental approbation is missing or withdrawn, some substitute is found, but since approval in any form is a treacherous and capricious ally, dependence on it creates an obvious insecurity. The normal increase in the strains of the environment accentuates this insecurity. Exposure to temptation increases, while relaxation of restraint is made to seem more alluring by the examples of the unpunished self-indulgence of others. Thus conflicts are created and heighten the already existing tension.

This summary has included the normal preface to adolescence which usually ends in normal emancipation or revolt. It has also indicated the pattern of the primitive response which often persists in the sensitive individual determining his type of maladaptation to life. If in early adult life the individual cannot drop his emotional dependence and his overvaluation of sensations, his stabilization is maintained on an inadequate level and complete integration is absent. His thinking is largely influenced by feeling; his psychologic and physiologic reactions are characterized by exaggera-

tion or even violence, and equilibrium is maintained at an extravagant cost of constant self management. Normal reactions, such as resentment and hate, are inconsistent with his idealistic codes and are suppressed. Obstacles to progress are never tolerated with poise and security but are met with grim determination and a rigidity of purpose that exhausts the individual and often causes secondary somatic or vegetative symptoms. Underneath the appearance of moderate self assurance that is maintained by success achieved under auspicious circumstances or at unreasonable cost, there lies a welter of conflict. Self pity, as a protective mechanism, supplements in large part the persistent drive for approbation. Enjoyment and contentment are dependent on tangible success and are seldom if ever related to relaxation or ease. A drive to be right at all costs and in all ways develops an intolerance of attitude that further complicates the individual's life.

It is my impression that this form of maladaptation is productive of such a state of masked tension that the individual is unable to withstand any moderate degree of frustration and loses his resistance to the normal physiologic affective depressions. No matter what the precipitating cause may be, the neurotic response of this type of individual usually is a depression, and, while it is common to speak of this as a reactional condition, I question the advisability of such a nomenclature, since it is not an impossible environmental situation which by its severity causes the person to collapse, but a specific disability in the patient due to his inferior technic in living and consequent inability to withstand any moderate obstacle.

The symptoms prodromal to the active depression are of considerable significance. The underlying maladaptation is usually unrecognized by the patient, but he recognizes that something is amiss and attempts to surmount his uneasiness by redoubled efforts at self management, thereby aggravating his condition by the abandonment of rest and relaxation. Any number of alarming sensory symptoms appear and perplex the patient. Frequently the depressive symptoms begin only when the patient is no longer able to stand this uncomfortable condition. Finally, however, the depression develops and is less well tolerated than the physical discomfort, since its associated psychologic dysfunction renders the individual incapable of any task requiring mental application. Such a state represents the failure of the individual in his self management and, as a patient, he succumbs to illness with resentment, intolerance and despair.

This attitude of resentment toward the malady is an important diagnostic feature, since it often differentiates this condition from the manic-depressive psychosis wherein the patient accepts the illness as an inevitable punishment for his unworthiness. Probably the difference between the psychoneurotic depression and other forms is not one of degree in a similar or the same process, although one may fuse into the other. Possibly the difference lies in the attitudes and inner experiences of the individual. Certainly the psychoneurotic depression is usually more clearly and closely associated with the patient's dynamic maladaptation and is less closely dependent on so-called mood swing. It is often impossible to make a differential diagnosis—certainly there are no pathognomonic signs or symptoms.

In the psychoneurotic depressive state the symptoms are less constant than the attitudes of the patient. Feelings of unreality and even false beliefs and fixed ideas may appear in transitory episodes. Suicide may

become a problem as an expression of the patient's resentment toward the world that has threatened his progress toward success. The patient accepts his pessimistic interpretation of his present status as a true representation of the future, believing that others recognize the validity of his assumption but are too kind to acknowledge it. Suspicion follows and leads him to avoid social contacts. When the disturbance in cerebration causes failure in attention, and indecision becomes marked, the patient fears that he is "losing his mind." He views all bodily and sexual symptoms as indicative of a failing physical apparatus. These fears, added to the anxiety, further increase the tension to the point at which agitation may result.

The patient's attitude toward his illness presents a difficult picture. While bent on proving the seriousness of his disability as demonstrated by the unfavorable comparison of his present with his past performance, he appears unable to endow this form of illness with any of the characteristics usually associated with other disease processes. He is at first intolerant toward the stated cause of his illness, he has no faith in psychotherapy and has little or no interest in the significance of his symptoms.

Lack of time restricts the discussion of treatment. I shall, however, refer to some of the major points. Therapy has certain phases. Attention is first centered on the explanation to the patient that his illness is a condition resulting from the strain of the preceding maladaptation. Repeated emphasis should be given to the favorable prognosis. Attention is next given to the education of the patient for an understanding of the normal function of the central nervous system and its correlation with the mental processes and inner experiences of man. The presence of the many sensory symptoms provides ample material for the practical explanation of the interrelationship of the physical and emotional factors. Following this informative phase of the treatment there is a period in which the patient's actual maladaptation and the critical problems that have developed as a result of this neurotic maladjustment are considered and formulated for a practical insight. The last stage of the treatment is centered around the reeducation of the patient for a better objective adaptation.

This categorical outline of the treatment has to be adapted to the patient and correlated with the various progressive stages of his convalescence. The initial period of frank emotionalism often ends in a brief phase of false optimism resulting from the reassurance and the superficial insight that the explanation of the nature of the illness has provided. However, with this decrease in depression the patient becomes more aware of the underlying anxiety and apprehension. His attention becomes focused less on self and increasingly more on his physical and psychologic environment. As he becomes more objective and begins to attain insight, an alarming sense of discouragement often appears and is confused with the former sense of depression. It is at this stage that the patient begins to acknowledge his actual problems and may even sense the close relationship between these and his maladjustment. This period should include a frank and searching survey of the patient's life by the patient and the physician, with the latter guiding and interpreting the emotional reactions of resentment and rebellion that may result from the material exposed. Subsequently insight must be formulated and applied for a better adaptation. Until some definite degree of achievement in the practice of

his new insight is attained, the patient seldom regains any of his sense of well being. During this phase the patient requires great supervision and support lest his discouragement and petty failures precipitate a chronic anxiety state. It is imperative that the relatives be educated to the needs of the patient during convalescence lest any competitive situations with those nearest him develop.

I should like to return for emphasis to the first and last phases of the treatment. It is expedient to stress repeatedly the definition of the nature and purpose of the illness until the patient has come to accept it as a fact before beginning any discussion of the more obvious emotional and situational problems. If the patient can be brought to a realization that the illness is a result of a long period of strain, he is then in a better position to accept the necessary therapeutic requirements of rest and temporary relinquishment of all responsibility until some degree of total efficiency has been restored. In the last stage of treatment the patient's attempts at rehabilitation should be directed toward a fractional resumption of his normal life. He must be protected from the influence of an elation during this period, since the initial attempts at normal adaptation should be made while the patient is still sobered both by his illness and by the import of his newly acquired insight.

SUMMARY

1 As a variant of the psychoneurotic maladaptation, the psychoneurotic depression is characterized by emotionalism and sensory discomfort indicative of a thalamic dysfunction.

2 Environmental strain acts only as a precipitating cause of the depression.

3 The fundamental maladaptation represents a faulty use of the total equipment and is often due to persistence of immature patterns of response.

4 Treatment varies only slightly from the usual treatment of the psychoneuroses. It should be directed primarily toward reeducating the patient to understand and use his normal equipment more completely, objectively and easily.

ABSTRACT OF DISCUSSION

DR WILLIAM NELSON, St. Louis. While what I have to state embraces certain points of divergence of views, I want to pay tribute to Dr. Kimberly's elucidating and terse presentation. I can't think of a psychoneurosis as developing always out of a parent-child relationship. I accept Dr. Kimberly's view of the inadequacy of the personality to meet life's situation on the part of the individual who becomes psychoneurotic. One thinks, of course, of the early experiences of an individual in connection with parental relationships or parental substitutes. However, there are certain things in the individual who is potentially inadequate, anatomically and physiologically as well as psychologically that make for failure in his adjustment. These factors may be many or few. There are certain states that tend to induce an attitude of psychoneurosis. I like to think of the psychoneurosis as a mode of dealing with one's experiences rather than based on its etiologic development, and think of the etiologic evolution in terms of a rather manifold experience coming to an organism in life that is not integrated properly and not able adequately to deal with those experiences. Many different situations in life that tend to develop this must be included. I have some well authenticated cases of psychoneurosis, from a rather close analysis in which the earlier childhood of the individual has been of a fairly normal character. I say "fairly normal" in proportion to the experiences that that individual has had come to him. However, there are certain stresses in life to which the potential psychoneurotic is not subjected in earlier life that come later,

and so the psychoneurotic attitude may not be manifest until later, whereas a potential situation does exist. So that I would rather shift the emphasis in psychoneurosis to have its meaning in the mode of dealing with the experiences rather than in the character of evolution, because the basis for evolution, as I say, comes from many different aspects. I must think, then, of the psychoneurosis as a disparity between the adequacy of the individual and the experience that he has had, and I must think of it as a mechanism of escape from a situation. Therefore it constitutes a fabrication, a substitution, and the individual fools himself into believing that certain factors are responsible for the situations that do not exist. So far as the treatment aspect of the disease is concerned, I think that Dr. Kimberly's is quite satisfying. First, the analysis of the situation, having the patient conversant with the problem, before remedial measures are attempted. Second, the plan of persuasion and acceptance either by direct or indirect approach in bringing about an expansion of the personality.

DR. CHARLES H. KIMBERLY, Stockbridge, Mass. I think that perhaps I have been a little too hard on the parents. I agree that many of the psychoneuroses seem to be escape mechanisms but it is my impression that this type of neurotic depression is more a result of the individual's drive for perfection. I think that I have indicted the parent too severely, not meaning to do this as much as the whole environment of childhood, when the patient-to-be begins to think that it is necessary for him to be perfect, he wears himself out trying to do everything that is right. I think that I accepted the point that it is not the parent entirely but, perhaps, the whole overprotective aura of childhood, the aura that is trying to develop this person into something he probably has no chance of ever being.

PRESENT STATUS OF THE X-RAYS AS AN AID IN THE TREATMENT OF GAS GANGRENE

JAMES F. KELLY, MD

AND

D. ARNOLD DOWELL, MD

OMAHA

In August 1928 Dr. J. R. Dwyer, one of the attending surgeons at St. Catherine's Hospital in Omaha, came to the x-ray department and inquired whether we had in the x-ray or physical therapy departments anything that might help him in treating a serious case of gas gangrene. The patient was a young man who had injured his knee in an automobile accident. He was in his twenties and, though a very robust individual, surgical consultants had advised against operation because the disease had extended to the groin. The patient was delirious and any surgical procedure seemed out of the question. We replied that there was nothing definite that we knew of but suggested that since the patient could not be moved from his bed we might use the mobile x-ray unit. He gave us permission to treat the man by any method that we thought might be of value and we used the mobile unit and the technical factors shown in table 1.

To those accustomed to giving x-ray treatments this seemed like an awfully small dose when a depth factor was desired, but the response was so remarkable and the recovery so rapid that the incident remained in our memory and, in a few cases following this similar treatment was given with the same startling results. In all, over a three year period, eight cases were treated which we shall call the first series. Table 2 shows the results obtained.

From the Department of Radiology, Creighton University School of Medicine.
Read before the Section on Radiology at the Fifty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1936.

In the first series there were eight cases in which x-ray treatment and gas bacillus serum were given. In this series there were two deaths. Further analysis showed that both of these deaths occurred in the cases in which the trunk was involved. Recovery occurred in all six cases in which the extremities were involved.

The conclusions drawn after analyzing the results in the first series were that the x-rays were very probably

of definite value in the treatment of gas bacillus infection when the extremity was involved but, since death occurred in both cases in which the trunk was involved, certainly there was no evidence of its value in these cases. However, realizing that we used a very low voltage type of radiation, we thought that by increasing the voltage and the depth dose we might be more successful in the future when the trunk was involved if we gave a heavier type of radiation. The recommendations we¹ made on reporting our first group of cases before the Radiological Society of North America in 1931 was that more cases be treated with x-rays when the opportunity presented and that if the trunk was involved the treatment given was to be with greater voltage and greater depth effect than that employed in our first series. After a period of three years during which time we treated two cases, one in which an extremity and one in which the trunk was involved, both patients living, we wrote letters to several colleagues who had treated cases and collected as much data as possible on their work. To our two cases we added thirty more by this method. These thirty, with our own two, we put into the second group of cases, which we shall term the second series.

In the second series, of thirty-two cases treated with the x-rays, serum was administered in only thirty cases. However, we were mainly anxious to know the effect of the x-rays in the trunk cases as compared with extremity cases, so we divided them accordingly. There were eight cases with trunk involvement and all eight patients lived while of the twenty-four with extremity involvement five died. These results were somewhat contrary to the results in the first series. The results in the first series would lead us to believe that recovery should occur in all cases in which an extremity is involved and that death should occur in all trunk cases, while results in the second series would lead us to believe that recovery should occur in all the trunk cases and that death should occur in at least some of the extremity cases, since there were five deaths in this group.

Further analysis of the extremity cases in the second series brings out the facts shown in table 4, namely, that there were thirteen cases of the twenty-four in the extremity group in which amputation was not done and the thirteen patients lived, and out of the remaining eleven extremity cases in which amputation was done only six patients lived and five died. This table shows the high mortality in this group of cases.

The proportion dead in this small series who had amputation was 45 per cent. We then combined all the cases in the first and second series and they are shown in table 5. The figures in this table show the relative mortality in the trunk and extremity cases of the first two series of forty patients. The table shows ten trunk cases and thirty extremity cases. The two dead in the trunk group occurred in the first series and we believe that as far as x-ray therapy is considered the result may be attributed to inadequate treatment. The next fact evident is in the no amputation group, and this is indeed startling. In the extremity group of seventeen cases in which amputation was not performed there were no deaths, seventeen cases of gas bacillus infection with 100 per cent recovery. In the extremity group in which amputation was performed the result was not so good, there were thirteen cases with five deaths, or a mortality of 39 per cent, and this is about the usual mortality in other series reported in the literature.

The reason for the high mortality in the second series in the extremity cases led us to investigate the hospital records of the five patients who died and it brought to light the following facts:

1 The first man died two and a half hours after the ligature sloughed off a large vessel in the stump on the ninth day. He had apparently recovered from gas gangrene. This might be recorded as an accidental death.

2 The second man died of a pulmonary embolism on the twenty-third day, the embolism followed some repair work on the stump. He also had evidently recovered from gas gangrene.

					6	5	45

3 The third man died on the third day after admission. He received only two x-ray treatments and failed to rally after an amputation. He had been severely injured. Shock was undoubtedly a factor in this man's death and he had insufficient x-rays to be properly considered as having had x-ray therapy.

4 The fourth man received 100 roentgens the first day and 90 roentgens the second day of his disease and no further x-ray treatment, dying on the fifth day, eight hours after an amputation. This was insufficient treatment, treatment should be given twice each day for at least three days.

5 The fifth man was one on whom the admittance diagnosis was diabetes mellitus with impending coma. He had a gas

bacillus infection in a diabetic ulcer. He died on the third day following an amputation, after receiving only two doses of x-rays. This also was not sufficient treatment. The post-mortem showed extensive bronchopneumonia.

In a final analysis of these five deaths in the second series one might honestly eliminate two of the five cases in which death occurred, as far as gas bacillus infection as a cause of death is considered. For instance, the

5	5		0	0

first man who died was one who died two and one-half hours after the ligature sloughed off a large vessel in a stump on the ninth day. He obviously bled to death after he had apparently recovered from the gas gangrene. The second man died of a pulmonary embolism on the twenty-third day. The embolism followed some repair work on the stump. He also had recovered from the gas gangrene. In the other three deaths in the amputation group gas gangrene cannot so easily be ruled out as a factor, and these three deaths with the two deaths in the trunk cases in the first series make a total of five deaths due to gas gangrene in the first and second series.

Encouraged by the results obtained using the x-rays as an aid in treating gas bacillus infection in the first two series, we decided to send a questionnaire to radiologists² and surgeons throughout the country who we thought might have had some experience with the work and in answer to this questionnaire we received data on sixteen additional cases. All the sixteen patients lived and this is the result that we hoped to attain at the time we reported our first series—namely, that others throughout the country would treat gas bacillus infection with the x-rays when the opportunity presented itself and by this means the results of the x-rays would more quickly be determined. We hope of course that the day will come when all patients with gas gangrene when an adequate dosage of x-rays is used as an aid in treatment, will recover. We are encouraged to believe this is possible when we study the series of cases reported in answer to the questionnaire recently sent out.

2. For permission to include their cases and the assistance given through correspondence the authors are indebted to Drs. I. J. Faust, Tyler, Texas; J. Philip Cogley, McNicken, Blanchett and J. L. Stech, Council Bluffs, Iowa; Albert P. Condon, Charles Newell, Howard B. Hunt, H. F. Johnson, J. Dewey Bigard, Roy W. Fours, A. P. Overgaard and E. A. Connolly, Omaha; E. A. Merritt and Isidore La Triana, Washington; D. C. B. Weems, Turner, Houston, Texas; L. A. Milkman, Scranton, Pa.; W. O. Squires, Coffeyville, Kan.; James T. Case, Chicago; Irvin I. Levi, Anniston, Ala.; Fred M. Hodges, Richmond, Va.; and E. W. Power, Lincoln, Neb.

The results obtained in the third series are shown in table 6. All sixteen patients had x-ray treatments but only eleven had serum. All lived, so evidently the five in this group who received no serum recovered.

As regards the status of amputation this series adds definitely to the opinion we have held for some time, namely, that it is an unnecessary therapeutic procedure. There were twelve patients who did not receive amputation, and all twelve lived. Two patients in the series received amputation and lived regardless of that fact (table 7).

In table 8 the mortality rate of the three series is compared. In the first series the death rate was 25 per cent. In the second series it was 9.3 per cent and in the third series it was 0 per cent.

The question of the use of serum is still undetermined. In the first series all patients received serum. In the second series two patients received no serum and recovered. In the third series five patients received no serum and recovered. Table 9 shows the total number of patients treated and the total number not receiving serum. All patients who did not receive serum lived. However, in spite of this we do not see fit to recommend the omission of the use of serum at this time. We also recommend the use of tetanus antitoxin, as tetanus developed later in one case in this series in which serum was omitted. The tetanus developed during the patient's convalescence after the gas bacillus infection had subsided. The patient also recovered from the tetanus (table 9).

With regard to amputation we are very emphatic in our belief that amputation is not a therapeutic procedure for gas bacillus infection.

There were forty-four cases in which the extremity was involved. There were twenty-nine in which amputation was not performed and all twenty-nine patients lived. Out of the fifteen who had amputations, five died, a mortality of 33 1/3 per cent. In these five we included the case in which the ligature sloughed off a large vessel on the ninth day following amputation and

the case in which embolism occurred on the twenty-third day following recent repair of the stump. They are included in the amputation deaths but not included in the gas gangrene deaths as the patient had evidently recovered from the gas bacillus infection (table 10).

In table 11 we have tabulated the mortality rate in the three series. Of fifty-six patients fifty-one lived, five died of gas bacillus infection, giving a mortality of 8.9 per cent. We feel that this mortality rate compares favorably with any series of gas bacillus cases so far reported in the literature.

We attempted to do some animal experimentation using guinea-pigs, but we could not determine anything to our satisfaction as it seemed to us that the pig is too small an animal to inject with the virulent gas gangrene and then attempt to cure it with the γ -rays. If a real active strain of gas bacillus organisms was used it traveled so rapidly that it was soon necessary to treat most of the pig, and the combination of general body

Number of Cases	Living	Dead	Per Cent Dead
56	51	5	8.9

irradiation left too much undecided. Some pigs got well and some died and in the end we determined nothing. The question of the use of serum is also unanswered. At the time of our previous reports we recommended that gas gangrene serum be used and we still recommend that procedure, though there are several cases in these three series in which serum was not used and still recovery occurred. Probably some accurate experimental work on some suitable animals can answer the question of whether or not serum is required when γ -rays are used.

In concluding, it seems fair to state that the γ -rays up to this time seem to be definitely established as an aid in the treatment of gas gangrene both in extremity and in trunk cases, but it seems desirable to use serum and other measures and refrain from amputation until the patient has recovered from shock and from the gas bacillus infection. Amputation may then be necessary in a badly damaged extremity. In one case in our series this was done and gas gangrene recurred after the amputation. This area was immediately treated and the gas infection subsided. Since there is so much shock connected with amputation and furthermore since the diseased area is not all eliminated by some of these amputations, it again seems worth while to omit amputations as an obsolete therapeutic procedure for gas bacillus infection.

CONCLUSIONS

If one may be permitted to draw conclusions from such a small series of cases it seems to be definitely certain that γ -ray treatment is indicated in gas gangrene, both in extremity and in trunk cases, that the treatment should be started as soon as the disease is suspected and be given throughout its course, twice each day for at least three days.

Since infected tissue was left behind in many of the cases in which radical surgical operation was per-

formed, it raises the question as to what good the surgery really does. Then the mortality of the patients operated on is so terribly high as compared to those not operated on that again the use of amputation seems to be a distinct disadvantage.

One child 11 and one 12 years of age in the second series recovered after losing an arm and both had active gas infection above the site of the amputation, so the disease was not all eradicated by surgical procedure. The children recovered in spite of amputations but lost an arm.

The dark appearance shown by the involved tissues does not indicate a true gangrene, and it clears up following successful irradiation. It is probably localized cyanosis.

One should not be discouraged and think the patient is beyond hope when one is first called on to treat him, as this work was started on material of that type, when the surgeon had his back to the wall, so to speak, when the case looked hopeless, in other words, the type of case all radiologists are quite familiar with in the inflammatory group.

 γ -RAY TECHNIC

The γ -ray treatment should be given morning and evening over a period of at least three days and of sufficient voltage to insure penetration of the involved tissue from 90 to 100 kilovolts on an extremity, 1 mm aluminum filter from 130 to 160 kilovolts on the trunk with increased filtration, about 100 roentgens per treatment over each area.

- Finally 1 Use γ -rays in all cases
- 2 Use serum unless there is some contraindication to the use of serum present
- 3 Use tetanus antitoxin
- 4 Use local surgical procedures and antiseptics as indicated
- 5 Do not amputate for gas bacillus infection

ABSTRACT OF DISCUSSION

DR EDWARD H SKINNER Kansas City, Mo. My experience has been limited to the diagnostic features of this condition. I know of only two cases in the last four or five years within this territory. This is a condition which automatically diagnoses itself and if one does not know how to diagnose it early on the γ -ray film one certainly obtains gross postmortem evidence. The array of cases that Dr Kelly has reported is most convincing. The interesting feature is Why are there so many cases in his territory? Rhinehart, with all the cases that he has diagnosed around Little Rock has not treated any cases. He refused to open the discussion because he said he had never treated any cases. This situation seems to be somewhat unusual. With the sporadic appearances of these cases in certain areas and the almost epidemic appearance of them in other spots it is probably not fair for the roentgenologist to assume too much responsibility.

DR JOHN J FAUST Tyler Texas. I wish to emphasize that the surgeon not only does not need to amputate as Dr Kelly has stated, early in the disease but that the slashing of tissues for drainage is not indicated either, in spite of the teaching in the older textbooks. The blood supply to the area would be thus damaged, the infection spread and repair delayed. No longer is this infection an indication for an emergency operation. Cultures in my cases showed that not all of the gas-forming organisms are provided for in the serum prepared by Parke Davis & Co, whose serum was used. Two of the cases in which cultures were taken were *Bacillus clausitridium* infections. Since the serum was not for this organism it is possible that the γ -ray therapy may have been entirely responsible for the cures. The serum was labeled as specific

for B. Welchii and Vibrio septique. It is obvious that a serum cannot be prepared to be effective against all of the gas-forming organisms. In two cases cultures were positive prior to the treatments, but cultures revealed no gas-forming organisms after the patients had been given x-ray treatments. I heartily agree with Dr. Kelly in urging that the treatment of patients be carried on regardless of how far the cases are advanced. I have been criticized for stating that a portable x-ray machine may do the work. This is a condition demanding urgent consideration, and time lost in calling for a radiologist from a distant city as some one suggested might be fatal. By actual calibration Dr. Landauer, a physicist found that a portable machine will deliver 45 roentgens per treatment. I am not certain that a heavier voltage is indicated. Frequent irradiation at eight-hour intervals maintaining more nearly a saturation dosage in the affected area may be adequate. In view of the fact that one of my patients had both gas gangrene and tetanus in spite of the prophylactic dose he was given, one wonders whether the proper dose was given or whether a larger dose is not indicated in such cases.

DR. W. WARNER WATKINS, Phoenix, Ariz. Because of my commenting at staff meetings of the hospitals in which I work on this work of Dr. Kelly's, one of our surgeons, in desperation was induced to try this method. The case was an amputation not primarily for gas gangrene but for a serious crushing injury to the leg. The patient developed gas gangrene in the stump below the knee and it spread to the thigh as far as the hip. The surgeon remembered the comments and called for x-ray treatment. Two treatments were given and the effect was dramatic, with an immediate drop in temperature, no further extension of the gas infiltration, and a fairly prompt recovery. This surgeon has raised the question of treating all compound fractures with x-rays to prevent gas gangrene. I have not been able to say whether it might or might not prevent the development of gas bacilli in tissue. I should like to know what Dr. Kelly thinks about this.

DR. JAMES F. KELLY, Omaha. In answer to Dr. Skinner's question as to the epidemic feature of this disease in and about Omaha I must call attention to the list of men who contributed to this series of cases, showing that they are from various parts of the country. Only about eight of these cases in a period of eight years are from my own service. Those who contributed are named in the paper. Concerning the question of diagnosis in Dr. Rhinehart's cases, since they all showed gas in the tissues and had clinical evidences of gas gangrene they should be considered gas bacillus infections. I do not care to enter into the bacteriology of this disease because I do not know enough about it. If they have an infection with a gas-forming organism they should be treated. Concerning the question of Dr. Watkins as to the value of the x-rays in prophylaxis I wish to state that one patient in this group received a treatment on admission to the hospital and one on the second day. No further x-ray treatment was given and he died on the fifth day. The x-rays did not prevent the disease in this case. I do not think the x-rays should be depended on as a prophylaxis but should be used throughout the active course of the disease. It was intended to go into the problem of prevention in guinea-pig experiments but we could not get results consistent enough to warrant any conclusions. It is helpful if one can get surgeons so enthusiastic that they will turn the cases over to the radiologist before the gas bacillus infection appears; then one can watch them, treat them earlier and have a better chance to cure them. The number of exposures necessary to cover the infected area varies but all the involved tissue should be treated. At a distance of 15 inches one may not cover the entire field if not two or three exposures are made. The entire extremity should be treated.

Milk Fat.—The fat of milk is already emulsified and so is more readily available to the body than the fats of other common foods except eggs. But the outstanding nutritional advantage of milk fat over other common food fats is the association with it of the fat-soluble vitamins, particularly vitamin A.—Sherman H. C. Food and Health New York Macmillan Company 1934

OSTEOMYELITIS AT COOK COUNTY HOSPITAL

WITH AN APPRAISAL OF ORR'S METHOD OF TREATMENT

MARCUS H. HOBART, M.D.
EVANSTON, ILL.
AND
DONALD S. MILLER, M.D.
CHICAGO

At a meeting of the Chicago Orthopedic Club the winter of 1935 at which Dr. H. Winnett Orr spoke on his treatment of osteomyelitis there was considerable discussion pro and con as to its value. Several different views were expressed. Some claimed unequaled good results with this method, others unrivaled poor results stating that it was no better than other ways. As a consequence no definite conclusion could be reached.

It was determined, therefore to review the record of cases of osteomyelitis treated by Orr's method in the orthopedic service at Cook County Hospital with the hope of throwing more light on the subject. Hence this compilation.

Fig. 1—Syphilitic osteomyelitis of the skull

The orthopedic service of Cook County Hospital is divided among six physicians. Most of the cases of chronic osteomyelitis together with some of the acute ones, are sent to the orthopedic service, but occasional cases are treated in the general surgical services, of which there are about twenty-two. This discussion is confined to the orthopedic service since it was felt that this was sufficiently diversified to give a rather general view.

As many of these patients comprise the ignorant poor the disease often was neglected, so that the cases are apt to be as severe and hard to cure as could be found in any group throughout the country. Therefore, if these could be cured by any means the results among private or educated patients should be better.

Then too since there are six attending surgeons handling these cases the personal variation of carrying out Orr's method should give an index to its general value.

From the surgical service of Northwestern University Medical School and of Cook County Hospital, Chicago.
Read before the Section on Orthopedic Surgery at the Eighty-Sixth Annual Session of the American Medical Association, May 14, 1935.

There is an enormous amount of literature on the treatment and results of osteomyelitis. The various methods of treatment have all had their period of advocates with varying degrees of successes. The Orr method of treatment seems to have outlived the critical eye and is still the accepted method. The reader is referred to the articles by Orr¹ and Hey Groves²

Fig 2 (case 1)—Squamous cell carcinoma formed in osteomyelitic ulcer

Although more than 375 patients have been operated on and asked to return for follow up, only one third have responded for a final check up. It may be assumed, therefore, that the majority of these patients may have become symptom free, and hence their absence. The cases reported here number 108, with 135 admittances to the hospital. The patients are referred to the outpatient orthopedic clinic from the examining rooms and consequently acute osteomyelitis is seen usually in the surgical wards as emergencies. Adults by far outnumber children since the latter are admitted to the children's ward.

ETIOLOGY AND COURSE OF THE DISEASE

The greatest percentage of cases was directly due to trauma of one sort or another. It is obvious that industrial hazards and modern methods of conveyance still contribute to the majority of these cases. Contact osteomyelitis in spite of the careful work of Koch,³ Mason⁴ and others still remains an important etiologic factor in osteomyelitis. Direct surgical osteomyelitis cases following open reduction of fractures and the like reach a high percentage.

The usual course of the direct type of osteomyelitis is one having an uneventful period of convalescence, requiring one or, at the most, two operations for a

cure. By this type is meant those cases of trauma following compound fractures, or direct implantations of bacteria following cuts and open wounds, frequently found in civic and industrial cases. No metastases have been seen following this type.

The patients with a hematogenous acute type follow a definite up and down course, are frequently readmitted for subacute inflammations of soft tissue and bone, and not infrequently remain invalids for life. Several cases have been seen in which the bones show extensive necrosis with bone abscesses but without a single complaint from the patient.

The extension form of osteomyelitis presents marked local manifestations with extensive bone necrosis and is frequently found in soft tissue infections of the hands.

The acute hematogenous type occurring in children is by far the most malignant in character, more toxic generally and recurs both locally and metastatically more often than the direct type. These patients return frequently, suffer skin infection and are subject by this chronic sepsis to anemia and amyloidosis. The contact osteomyelitis responds best to treatment, a thorough bone cleansing usually sufficing. The extension osteomyelitis is more disabling, requires soft tissue drainage and in many cases produces large massive bone necrosis.

Two cases of syphilitic osteomyelitis are reported, one involving the skull (fig 1), the other the ankle. Both patients had draining sinuses with pain. Each case responded well to antisyphilitic treatment with potassium iodide and mercury.

The majority of cases in this group of 108 occurred in adults between the ages of 20 and 40. Those of children and preadolescents were seen infrequently because of treatment in other wards.

Fig 3 (case 2)—Squamous cell carcinoma formed in osteomyelitic ulcer

COMPLICATIONS AND SEQUELAE

As shown in table 2, complications are not as uncommon as was supposed. The three cases of squamous cell carcinoma arising from chronic osteomyelitis are important because radical treatment in the form of amputation seems to be the only method of choice. Two of these occurred in sinuses of one and one-half years' duration (figs 2 and 3). The third occurred after a chronic draining sinus of forty years' duration.

(fig 4) It would seem, therefore, that chronicity of drainage with irritation to epithelial proliferation, as Brunschwig⁵ brings out is not the primary cause but rather a constitutional diathesis of some sort. The type of malignancy reported in all three cases is that of a hornifying squamous cell carcinoma.

Fig. 4 (case 3)—Squamous cell carcinoma formed in osteomyelitic ulcer.

The second group of complications was that of bilateral toxic neuritis of the eighth nerve occurring in two male patients, one 16 and the other 17 years of age. These two patients had hematogenous generalized

osteomyelitis deafness occurring rather suddenly from six months to one year after the bone infection.

The third group of complications is that of pathologic fractures two in number. One occurred after neglect of treatment in a woman aged 50 in whom an acute

suppurative arthritis developed, with indifferent conservative treatment a fracture developed at the lower third of the humerus. The second patient, a man aged 43, developed a rather sudden hip condition, following tonsillitis, and two weeks afterward fractured the neck of the femur. The fourth complication was a case of toxic encephalitis in a child aged 9 years, simulating a brain abscess. The abscess was drained through a subtemporal decompression. An uneventful

TABLE 2—Complications and Sequelae of Cases Reported (108)

recovery ensued. The patient is at present symptom free both from the bone infection and from the cerebral involvement.

TECHNIC OF TREATMENT

We have attempted to follow Orr's dictum of treatment with proper drainage and rest. The cases of fever, pain and roentgenologic evidence of infection are opened widely and debrided but cautiously (fig 5) with an attempt to prevent further extension into normal bone. At times the cavity is swabbed with iodine and alcohol. Petrolatum packs are inserted loosely and a cast is applied. The cast is left on until healing occurs but occasionally is replaced by a new one. The outer dressings may be changed but the petrolatum

Fig. 5—Nonunion of tibia following debridement of osteomyelitis.

pack is allowed to remain for four weeks when it is removed carefully and a new petrolatum pack inserted. This is done to prevent the gauze from adhering to the wound. In recurrent cases with discharge but without pain more conservative methods are used and sequestrums are removed only under roentgenologic evidence. Sinuses of soft tissues are curetted and allowed to heal from the bottom. Brodie's abscesses are opened, normal bone being spared as much as

⁵ Brunschwig, Alexander. Epithelialization of Chronic Osteomyelitic Cavities. A Precancerous Lesion. Radiology 24: 62 (May) 1935.

possible. Very conservative measures are used to remove infected bone in cases of extension osteomyelitis of the hand.

COMMENT

Although the number of reported cases is relatively small, the results of this method are extremely gratifying. It is difficult to judge the healing powers of the various bones, the period of convalescence in healing and the general response of the patient because of the variability of the technic, the period of operability and the virulence of the organisms in the production of osteomyelitis. All that can be said is that this method has given 62 per cent symptom-free cases (table 1). Twenty-one per cent of cases treated by the Orr method failed to heal to date. Those cases treated by some modification of this treatment, i. e., without cast or without packing gave 12.5 per cent of cures in the sixteen cases reported.

CONCLUSIONS

1 The Orr method of treatment still remains the treatment of choice for osteomyelitis.

2 Hematogenous osteomyelitis shows no great advancement of cures, whereas direct osteomyelitis responds well to direct, thorough, bone osteotomy under proper conditions. Extension osteomyelitis still remains a problem of the general surgeon and, with the proper treatment of infections, osteomyelitis should be reduced.

3 Complications in this series are large. Three cases of malignancy of soft tissue (26 per cent), two cases of toxic neuritis of the eighth nerve (19 per cent), two pathologic fractures (19 per cent) and one case of toxic encephalitis (0.96 per cent) occurred in this series of 108 cases.

636 Church Street

ABSTRACT OF DISCUSSION

DR. R. J. DITTRICH, Fort Scott, Kan. From an analysis of the pathologic changes seen in osteomyelitis and the course of the disease, it is noted that there are a large number of variable factors which make the disease complex and the outcome uncertain. The most important feature in the treatment is adequate drainage and thus, together with immobilization in plaster casts, constitutes a method of treatment that is sound in surgical principle and consistent with ideas of infection in general. It may be said that no method of treatment is fool proof yet a strict adherence to the principles advocated by Orr will yield a high percentage of satisfactory results. It has been my experience to see more frequently local recurrences in healed lesions and metastases in other portions of the skeleton. There is no way by which these conditions can be foreseen or avoided. However, it is hoped that some method of immunologic therapy may be developed by which these complications can be effectively prevented and the morbidity of the disease thereby minimized.

DR. JACOB KULOWSKI, St Joseph Mo. My recent report from Steindler's clinic, includes 323 cases treated by the Orr method, in 65 per cent of which healing had occurred up to the time of this investigation, with a general mortality of less than 3 per cent. Twenty per cent of the patients were still under treatment, about 2 per cent required amputation and the result was unknown in about 11 per cent. In an earlier paper it was shown that the average period of convalescence until healing occurred was dependent on the following factors. In general lesions treated primarily or initially by this method averaged six months; those treated secondarily (after some other form of treatment had been instituted), nine months. Foci in the upper extremities healed in six and one-half months as against nine months for foci in the lower extremities. Lesions complicated by sequestrum or sinus formation, as well as infected compound fractures, healed in ten months. The most stubborn group showed a mixed bacterial infection and required almost

fifteen months. In this smaller series healing occurred in more than 76 per cent of the cases. The vast majority of these cases were in the subacute and chronic stages. There is more or less general agreement regarding the Orr method in these stages of the disease. Argument and some confusion continues relative to the acute hematogenous lesions. The pendulum is swinging toward conservatism in degree. It is helpful to remember that surgical intervention is not indicated until there is definite local evidence of suppuration. Perhaps early diagnosis and immediate drainage have been overemphasized at the expense of a careful evaluation of the surgical risk. The fault rests with the individual surgeon and not with this method. Common sense neglect of generally accepted preoperative rules of procedure reflects unfairly on and discredits sound axiomatic surgical principles of drainage. However it is also true that the conservative postoperative technic of the Orr method allows more extensive surgery in the acute stages in properly selected cases, than would otherwise be feasible. The Orr method meets all the therapeutic requirements presented by a disease in which chronicity and its attendant devastating sequels was formerly inevitable in about 80 per cent of survivors. This standardized universal method, suitable to the rank and file of physicians can combat a disease so apparently contradictory and variable in its clinical and pathologic manifestations. The entire clinical life history of the disease has been finally reflected in its complications which predominated the picture until more recent times. Now the dovetailedness of its phenomena is clearly evident, since the vast majority of sequels are dependent on the local skeletal situation. From this perspective there is a clinical harmony on the basis of which the Orr method was evolved and on which it must stand or fall, namely, the primary and secondary control of the disease.

DR. J. E. M. THOMSON, Lincoln Neb. The Orr method fulfils the requirements that have been outlined by most writers on this subject better than any other that I have been able to try, and I had my fling during the war at the Carrel-Dakin method, later at various antiseptic packs and dressings, and more recently at maggot traps only to swing back to the petrolatum pack. The method, from a practical standpoint, offers the patient more comfort during his period of convalescence and gives the physician or surgeon less anxiety and demands less labor in his care of the patient. Lastly, it is far more economical for the patient and also for the hospital, in the way of supplies and equipment in spite of the fact that one is often embarrassed by the fragrance that emanates from these cases, which after all, is far more distressing to the friends and relatives than it is to the patient himself. I am aware of the fact that a great many of these compound fractures and open wounds can be cleaned up thoroughly and closed and that they will heal by first intention. It hardly seems necessary to prolong convalescence by putting in a petrolatum pack in every one of these cases, because, should infection develop and the symptoms so indicate the wound could be opened and the Orr method applied. There are several rather interesting things about this paper that impressed me. First in making an assumption one should be very careful and have it well founded. For instance simply because of the fact that of the one third of the entire group of patients who came in for check up there were 62 per cent healed and symptom free, it would seem preposterous to assume that the other two thirds were cured. On the other hand had two thirds of the entire group come in for check up and been found symptom free, one might be willing to assume that the other third at least had as good a break as the two thirds who came in. I am sure that the authors did not wish to be misleading in this statement, and I mention the fact only in order that a correction may be made. Perhaps the most important feature of this paper was the fact that it called attention to the frequency of complications in osteomyelitis. To think of 7.36, or almost 7.5 per cent, of osteomyelitic patients having complications seems rather high, particularly in private practice. However, one should be apprehensive of these complications and ready to meet these problems as they arise. Lastly I think that the authors' deduction with respect to the fact that direct osteomyelitis healed more readily by the Orr method than did the hematogenous type is correct. This gives a basis by which one may make a prognosis in these cases that will have more chance of healing by the Orr method and gives an opportunity to judge what the outcome is going to be.

DR. EDWIN W. RYERSON, Chicago I read in the program A Report of Five Hundred Cases Treated by the Orr Method "What it boils down to is a report of about 125, and I think that is a little misleading

DR. JOHN PRENTISS LORN, Omaha I learned the first principles in the treatment of osteomyelitis under Dr. Moses Gunn as early as 1880. He taught that wide incision, adequate removal of the disease, and packing the cavity with crystals of boric acid cured a large proportion of the cases. From 1893 I practiced general surgery exclusively until 1922. In those earlier days the general surgeons handled osteomyelitis. I followed the principles learned from Gunn in securing early, adequate, maintained drainage. In the early years of the Nebraska State Orthopedic Hospital, as chief surgeon for a number of years, with Dr. Orr as associate I had many old, neglected, extreme cases of osteomyelitis in children. We found that in removing the gauze packings, then in general use, there was an elevation of temperature after every dressing and it took a day or two or three for these temperatures to return to normal. The question was: What could we do to avoid this? I had been dabbling with Beck's paste. I had an adverse reaction against Beck's paste. Then there were some who injected petrolatum undertaking to cure chronic sinus involvement in the same way—a failure, of course because unsurgical. I devised a means of pouring these gutters mostly in shin bones with petrolatum, covering with gutta serena tissue and allowing the discharge to find its way out from its edges. That unfavorable experience following the gauze dressings was eliminated, and they pursued a smooth course. In later years Dr. Orr amplified this petrolatum treatment. Indeed he must be given credit for having established a system that has been very successful, perhaps on a par with any other. Having been a general surgeon however, with the general surgeon's psychology, I had somewhat of an adverse reaction against treating all my osteomyelitis cases with petrolatum. In selected cases I did use it, but I sought to eliminate the major unpleasant objectionable feature—the odor. I melted petrolatum with 10 or 11 per cent of paraffin and used mostly boric acid petrolatum believing that it would stimulate granulations. I held this plug in with paraffin-linen mesh strapped on with adhesive plaster. As this soft material would exude through the mesh as the cavity became smaller it was scraped off with a sterile spatula and the wound margins were painted with mercurochrome because iodine smarts. The gauze pads were changed often. We didn't have the stench and we didn't have to move these patients out on the porch or out into the orchard. By changing the pads as indicated extravasation of discharges into the dressings or into the plaster was thus prevented and the very objectionable odor greatly minimized. Operators desiring to continue the petrolatum treatment may wish to accept this suggestion of mine.

DR. MARCUS H. HOBART, Evanston, Ill. Dr. Kulowski's figures agreed pretty well with ours: 65 per cent of cure in cases of osteomyelitis treated by this method. I agree with Dr. Thomson that the use of the petrolatum treatment in compound fractures seems unnecessary. The compound fracture can be opened later if infection is superimposed. As to assuming that the 200 odd cases that we didn't report were cured, I said at the beginning of the paper that a person might assume that they were cured, but they were not included in the 108 cases in the statistics that we compiled. As to Dr. Ryerson's remarks on the 500 cases I think that they are very well taken. Five hundred was the general impression that we had at first of the number of cases. When we got the compilation we found that there weren't that many, and an attempt was made to correct the title. I apologize for that title. It has been worrying me ever since it came out. As to Dr. Lord's treatment: early adequate drainage. I believe it is one of the primary and most important parts of this treatment and it is perhaps the thing that allows the condition to clear up. In the letters that we sent out five out of six of the attending men were unanimously in favor of Orr's method for the treatment of osteomyelitis. I may say that ten years ago when we started on the service, we hated to see a case of osteomyelitis come in because we felt once osteomyelitis always osteomyelitis. We feel that, with the Orr method of treatment, we can get at least 62 per cent of cures.

RESTORATION OF THE ORBIT AND REPAIR OF CONJUNCTIVAL DEFECTS

WITH GRAFTS FROM THE PREPUCE AND LABIA MINORA

GRADY E. CLAY, M.D.

AND

J. MASON BAIRD, M.D.

ATLANTA, GA.

Grafts from the prepuce and labia minora have not heretofore been used for conjunctival grafts and it is the ideal tissue as a substitute for conjunctiva. There is plenty of tissue available for such grafts and it has all the appearance of perfectly normal conjunctiva a very short time after it has been grafted. The graft from this source is very thin and contains no hairs and very little subcutaneous fat. It has a pinkish color and can easily be cut to fit the area desired.

Fig. 1.—Tumor recurrent after second surgical removal before conjunctival graft.

Skin grafts used in restoring conjunctival defects have been successful but are most unsatisfactory to the patient in that they are uncomfortable and unsightly, desquamation is always present, and there is most frequently a disagreeable odor. For those reasons this new type of graft seems to be an ideal substitute for the conjunctiva.

In the correction of symblepharon and the removal of large growths from the conjunctiva for which grafts are necessary, grafts from the prepuce and labia minora are ideal because they have the appearance of conjunctiva and do not desquamate. Grafts for such defects are cut slightly larger than the area to be covered and then with very fine silk, are carefully sutured in place. The conjunctival sac is then filled with boric acid ointment and a pad applied with not too much pressure. This is allowed to remain for three days; the dressing is then changed daily; the sutures are removed on the fifth day and the pad is removed after one week.

Read before the Section on Ophthalmology at the Fifty-Seventh Annual Session of the American Medical Association, San Francisco, May 14, 1936.

In restoration of the socket, the socket is opened and prepared in the usual manner and the graft is cut and shaped to fit the socket. Plenty of fine silk sutures should be placed at the margins of the lid and the graft placed in position, two double armed sutures being placed through the upper lid to hold the graft smoothly against the tarsus and the same sutures placed through the lower lid the sutures being tied on the surface of the skin. The socket should be well dilated and kept so for two weeks if an artificial eye is to be worn successfully afterward. For that purpose an artificial eye with a glass ball cemented to the back of the eye best fills out the socket. This is placed in the socket with plenty of boric acid ointment, the lids are kept sutured a pad is applied with pressure and left for four days and thereafter daily dressings with slight pressure are applied. The lids should then be separated at the end of two weeks and an artificial eye should be inserted at once.

The mucous membrane of the vestibule of the vagina (between the inner margins of the labia minora and the outer margin of the hymen) is smooth, glistening and devoid of glands and of hair follicles. Such a graft is easily obtained from this region of the female external genitalia, and subsequent healing leaves no deformity.

The field of operation is prepared with soap, water and a solution consisting of equal parts of acetone 5 per cent mercurochrome and alcohol. A quadrilateral incision is made within the vestibule between the inner margin of the labia minora and the edge of the hymen. The upper transverse incision is made at about the level of the upper margin of the vagina and the lower transverse incision well down near the center of the fossa navicularis. Two vertical incisions one near the inner margin of the labia minora and the other along the

Fig 2—Appearance after graft

outer edge of the hymen complete the quadrangle. In this way a strip of mucous membrane approximately 3 by 5 cm. in diameter, is easily obtained. There is very little bleeding at the site of the graft. The incision is closed with interrupted sutures of zero plain catgut. If necessary a similar graft may be obtained on the oppo-

site side. Healing in the cases done was by primary union without any deformity of the external genitalia. The skin from the prepuce is obtained by a circumcision, special care being used in the preparation, and as much as possible of the inner surface being employed, for here the skin is much more like mucous membrane.

Fig 3—Eye before surgical removal of hemangioma

In the reports of two cases, the first demonstrates the conjunctival graft and the other the restoration of the socket.

CASE 1—P. H., a healthy man, aged 35, first seen in June 1931 at the Steiner Clinic of Grady Hospital, had had a small tumor on the right eye at the outer canthus two years before. It had been removed surgically twice during that period, the last time being six months previously, and had recurred with much more rapid growth. Examination showed a large tumor of the ocular conjunctiva at the outer canthus, which was slightly elevated and about 6 mm. in diameter and extended across the limbus for about 1 mm. The tumor seemed to be slightly attached to the sclera, as it was not movable. The tumor was very vascular but not pigmented. A diagnosis of carcinoma was made and enucleation was advised, which the patient refused. One week later the tumor was removed and was found to be very adherent to the cornea and sclera near the limbus, but there was such a large denuded area that it was difficult to cover it with conjunctiva. This was done, however, and radium needles were planted under the conjunctiva and removed four hours later. The following day there was a sloughing of the conjunctiva and superficial layers of the sclera, this area 7 mm. in diameter, remained as such. July 9 the graft from the foreskin was used and sutured in place. The eye was filled with boric acid ointment and dressed on the second day. At the first dressing there was very little discharge and the graft seemed to be taking perfectly. On the fifth day the graft had a good color, the sutures were removed and on the seventh day the pad was removed with a perfect take of the graft, as shown in figure 2. The patient was last seen in April 1936 with no evidence of return of the tumor and suffering no discomfort from the graft. The use of radium produced a severe keratitis near the limbus which has given some trouble since, but there has been no discomfort from the graft.

The pathologic report by Dr. E. L. Bishop, pathologist of Steiner Clinic stated that sections showed sheets of partly hornified epithelial cells with pearls and spines. The cells were hyperchromatic and fused together. In one area the cells were much smaller and very hyperchromatic and almost spindle

shaped. Mitoses were not especially numerous. There was evidence of moderate infection, with a little connective tissue stroma and numerous lymphocytes.

The diagnosis was epidermoid carcinoma, grade 2, moderately sensitive in some portions.

CASE 2—Miss C. H., aged 22, was seen Jan. 13, 1933. At the age of 2 years a small reddish growth was noticed on the

Fig. 4—Appearance after removal of tumor

ball and lower lid. This gradually increased in size so that at the age of 15 the lower lid was markedly swollen and the eyeball was protruded. A tumor was removed at that time by a local surgeon. Following this the tumor did not reappear until five years before the present admission and then the swelling of the lower lid began to occur and gradually grew with an

Fig. 5—Socket after restoration by labial graft

increasing proptosis. Examination revealed a marked proptosis of the left eye, the ocular conjunctiva especially at the limbus below was swollen and a dark red. This was true of all the conjunctiva below and of the lower lid. The lower lid was markedly swollen and a tumor mass was easily felt. August 14 under surgical anesthesia an attempt was made to remove the tumor, which was diagnosed as hemangioma. An incision was made parallel to the border of the lid near the margin of the

orbit below, and the tumor, which filled the lower orbit, dissected out. The conjunctiva from the lower lid and part of the ocular conjunctiva were cut away with the diathermy current and the lower lid was allowed to become adherent to the eyeball. Figure 3 shows the tumor before operation. The result of the operation was striking, as shown in figure 4 but the eye was not freely movable, owing to the adhesion of the lower lid to the eyeball, and closure of the lids was not perfect. An exposure keratitis began to develop and a few months later the ocular conjunctiva nasally and above became involved in the tumor mass, radiation was used during this period with no reduction in the size of the mass but with loss of lashes and retraction of the upper lid, and by August 1934 the eye became so uncomfortable that enucleation was necessary. When the eyeball was removed it was necessary to remove all the remaining conjunctiva, since it was involved in the original tumor, the lids, of course, became adherent and there was no remnant of a socket.

July 9, 1935, the restoration of the socket with the mucous membrane from the labia minora was attempted. The socket was freed and dissected of any scar tissue, and Dr. W. R.

Fig. 6—Artificial eye in reformed socket

Holmes dissected the graft from the vagina giving us a graft 1 inch (2.5 cm) wide and 2 inches (5 cm) long, stating at the time that more tissue was available. This graft was very thin and had no subcutaneous fat. It was carefully sutured to the lid margins above and below and at the inner and outer canthus a ball was inserted with much boric acid ointment. The lids were sutured together and a pressure bandage was applied. The socket was not dressed for three days. At the first dressing there was only a slight discharge; the lids had separated except for the central area, which was left and daily dressing of boric acid solution was used. Slight pressure was kept up for ten days at which time the lids were separated and the ball was removed. The graft made a complete take and at that time had the appearance of a normal conjunctival socket. The socket after one month did not contract since a ball was kept in place but not enough culdesac was present below to permit the wearing of an artificial eye. September 8 a similar graft was obtained from the opposite side of the vagina and it was placed below. An incision was made along the lid margin below and the mucous membrane was pushed back, the lower lid was dissected up and the graft was sutured to the lid border and mucous membrane. The dressings were the same as in the previous operation. On the tenth day the graft had

made a perfect take, figures 5 and 6 show the socket, which has all the appearance of a normal conjunctival socket. There has been no discomfort or discharge, and there is no deformity of the vagina.

CONCLUSION

Tissue from the prepuce and labia minora are ideal for all conjunctival grafts, and enough tissue is available for the complete restoration of the socket. Such tissue has none of the objectionable features of ordinary skin grafts.

Clinical Notes, Suggestions and New Instruments

BRINGING OUTSIDE AIR INSIDE

AN INEXPENSIVE SUBSTITUTE FOR OXYGEN THERAPY

J. E. CREWE, M.D., ROCHESTER, MINN.

For many years, in cases of pneumonia or tuberculosis, and in a few cases of advanced cardiac diseases, I have used with excellent results the apparatus that is here described. The apparatus consists essentially of a small blower and a pipe about 2 inches in diameter. The blower is attached to an aperture in a board of adjustable length so made that it can be fitted beneath a raised window. The pipe extends from the blower to near the patient's face. The middle portion of the pipe is rigid but can be made of adjustable length. To this portion of the pipe is attached a cord and counterweight. The cord runs through a hook or pulley that can be screwed into the ceiling or into an overhead frame. The ends of the pipe are flexible. Thus, the pipe can be hung in any convenient position.

The purpose of the apparatus obviously, is to supply gently moving outdoor air directly to the patient. In extremely cold weather the patient's chest is adequately protected and sometimes a woolen cap is worn, but it is rare for patients to complain of the cold air. They obtain so much relief from it that they object to having the air supply discontinued.

The chief advantage of the apparatus is that it can be used where oxygen is not available because of problems of trans-

The apparatus in use in a home.

portation or of expense. The other advantage is that the atmosphere in the patient's room can be kept at a comfortable temperature and he lies or sits with his movements unhampered by heavy bed clothes or a tent. Moreover, it is sad to say that in many dwellings of our country the patient does not have a room to himself. In fact often a large family must live in one or two rooms. In such cases the atmosphere of the room must be kept warm in winter and is vitiated by heating stoves and by the breathing of other members of the family.

Those physicians who practice in rural districts which have been hard hit in recent years will appreciate the circumstances which first suggested to me an apparatus of the sort that has been described. I was called to see a child, aged 5 years, who had pneumonia. The child was cyanotic and the air in the small, tightly closed house was very bad because of the crowded condition of the house and the fumes from a kerosene stove. The outdoor temperature was -20°F . I asked the father to find if possible a piece of 3 or 4 inch pipe. He was fortunate in finding an old boiler flue about 7 feet long. A hole, large enough to admit the pipe, was cut in a board and the board was fitted snugly into a partly opened window. The cold air rushed in and almost at once the cyanosis disappeared. The simple apparatus was used until the child recovered.

Since then, on occasions I have reverted to this crude apparatus, for instance, in homes where electricity has not been available to operate the blower, I have used rain spout or any other pipe that could be procured and have fitted elbows to the external end of the pipe to catch the prevailing wind.

In one case, during an extremely hot spell, a patient, aged 75 years, who had pneumonia, was experiencing great difficulty in breathing. With all windows open and several fans running, he was not relieved. The pipe was attached to a window, all other windows were closed, and a spray from a garden hose was directed past the inlet of the pipe. At once the breeze of cool, moist, outdoor air that was directed near the patient's face gave much relief from air hunger. After that experience I attached to the inlet of the pipe an automobile hot water heater and caused cold water to circulate through it.

Considerable experience over many years has convinced me that, by the methods described, most patients can be given all the oxygen they require, in nature's own mixture. Recently the apparatus was exhibited at the meeting of the Minnesota State Medical Association and attracted favorable interest, particularly among rural practitioners.

ACUTE BRUCELLOSIS

DEATH FROM PULMONARY EMBOLISM

WILLIAM R. BAGLEY, M.D., SELMA C. MUELLER, M.D., AND ARTHUR H. WELLS, M.D., DULUTH, MINN.

Infections with *Brucella* organisms are being more frequently diagnosed in recent years than formerly, and the clinical and pathologic aspects of the disease are more widely recognized. The old names "undulant fever" and "Malta fever" are giving way to the more scientific term "brucellosis,"¹ mainly because the clinical syndromes of the three causative organisms, *Brucella abortus*, *suis* and *melitensis*, cannot be differentiated. Although patients having the disease usually recover, an occasional one succumbs. We are reporting here a case of Brucellosis having the unusual occurrence of fatal pulmonary embolism.

REPORT OF CASE

A white man, aged 46, an urban laborer, presented himself for examination because of progressive weakness and cough of three months' duration. The cough was unproductive. His appetite had failed and he had suffered from constipation since the onset of the malaise. He believed that he had been having fever a good share of the time, but he had continued to work in spite of marked exhaustion. The past history revealed nothing of note except an appendectomy nineteen years before and "gravel" in the right kidney following that.

The patient was well developed and seemed quite comfortable. The only physical phenomena of note were a temperature of 101.6°F ., pulse 80, blood pressure 108 systolic and 65 diastolic, marked oral sepsis, and chronically infected tonsils. Laboratory examination revealed a hemoglobin of 76 per cent, 3,930,000 red blood cells and 5,500 white blood cells, of which 59 per cent were polymorphonuclear cells, 40 per cent lymphocytes and 1 per cent basophils. The patient's blood serum agglutinated *Brucella melitensis* (*abortus*) antigen in a dilution of 1:320 on first examination and later in a dilution of 1:1,280. Blood cultures subsequently showed growth of *Brucella abortus* apparently of the bovine type.

During his stay in the hospital the patient's temperature ranged from 100 to 104 occasionally dropping to 99. He per-

¹ Evans, Alice. Chronic Brucellosis. J. A. M. A. 103:665 (Sept. 1) 1934.

spired profusely, soaking the bedclothes several times each night. On the fourth day of hospitalization, three teeth were extracted under local anesthesia, followed by some rise in temperature. On the eleventh and twenty-third days of his hospital stay, 50 cc. of whole blood from a brucellosis convalescent was injected intramuscularly. The patient seemed to be slightly improved for a few days, but his temperature still rose to between 101 and 102 each afternoon. On the twenty-fifth day of hospitalization he complained of a pain in the left thigh at 5 p. m. At 9 25 he suddenly experienced a severe pain in the left leg followed shortly by pain in the precordium, cyanosis and dyspnea. In spite of stimulants, nasal oxygen and artificial respiration, he died at 9 45 p. m.

At necropsy, an antemortem clot 8 cm. in length was found plugging the left pulmonary artery, and several fragments of the same clot were present in the right pulmonary artery. In the left femoral vein, 4 cm. below Poupart's ligament, remains of a thrombus were found. Both iliac and femoral veins showed smooth, noninjected internal surfaces free from inflammatory changes. Microscopic sections of the embolus showed the characteristic architecture of an antemortem thrombus entirely free from unusual inflammatory elements.

There were evidences of an active toxic or inflammatory process widespread through the internal organs. The posterior portions of both lungs showed a moderate diffuse congestion with frequent scattered neutrophils in the interstitial tissues and many pigment-laden phagocytes in the alveoli. The 2,400 Gm. liver showed a moderate diffuse neutrophilic infiltration of its sinusoids and rather frequent small focal accumulations of neutrophils and monocytes, at times obliterating native tissues. The soft granular dark red pulp of the 375 Gm. spleen was severely congested with red blood cells and contained many pigment-laden phagocytes and occasional neutrophils. There was a mild swelling of the epithelial cells of the convoluted tubules of the kidneys, with finely granular debris in the lumen but no inflammatory cell infiltration of these tissues. No ulceration of the intestine was found, but the mesenteric lymph nodes were slightly enlarged and soft. Throughout the entire body, no localizing inflammatory processes could be demonstrated. A guinea pig, inoculated with postmortem blood, showed no lesions after thirty days and blood cultures made at the same time remained negative.

COMMENT

In a search through the American literature we could find no references to occurrences of massive pulmonary embolism in patients suffering from Brucellosis and only casual mention was noted of the occasional occurrence of phlebitis. In the French literature, however, Roger and Audier² report cases of phlebitis complicating this disease, and reference is made to cases in which pulmonary embolism occurred.

In the case here reported, marked infection of the alveolar processes and gums was present. This apparently antedated the Brucella infection, and this must be considered a possible focus of infection for the subsequent development of phlebitis with resultant pulmonary embolism. Roger and Audier bring up the question as to whether phlebitis in these cases is due to primary localization of Brucella melitensis in the veins or whether the phlebitis is due to secondary infection. They are of the opinion that there occurs a venous localization of a melitensis septicemia. In this regard it is interesting to note that an occasional complication of brucellosis has been a vegetative endocarditis from which Brucella abortus has been isolated.³

Goshay⁴ has recently observed a case of brucellosis in which edema and cyanosis appeared about the face and head. He believes that a thrombotic process occurred in the deep veins at the base of the brain. His patient recovered.

Of particular interest in the case presented here are the acute and fulminating course of the disease, the drenching night sweats during the last month of illness, the marked oral sepsis and death due to pulmonary embolism without clinical evidences of phlebitis until four hours before death.

Special Article

USE OF THE DERMAL PARASITICIDES

FRED WISE, M.D.

AND

JACK WOLF, M.D.

NEW YORK

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—ED

In this article we shall confine ourselves to a discussion of the use of parasiticides in the parasitic disorders occurring in dermatologic practice. A discussion of the use of these remedies in diseases of nonparasitic origin would lead us too far afield, since it would embrace almost the entire field of dermatotherapeutics.

In the accompanying list are the most important members of the group of drugs referred to as the parasiticides. They form the basis of present-day antiparasitic therapy. There are other remedies, some of which will be mentioned in the text, but these are purposely omitted in the list. The reasons for their use will be given. A thorough knowledge of the actions of a few valuable remedies and a sufficient acquaintance with their use is more important than the haphazard application of many. Much can be achieved by the proper combination of two or more of these medicaments by variations in their respective percentages and by the choice of the proper vehicle. For these reasons alone, even if for none other, many proprietary remedies may be justifiably condemned.

The parasitic group of diseases forms a not inconsiderable percentage of the total number of cases seen

Most Important Parasiticides

Peruvian Balsam	Sodium Thiosulfate
Chrysarobin	Betanaphthol
Pyrogallol	Sulfur
Iodine	Resorcinol
Mercury Bichloride	Salicylic Acid
Ammoniated Mercury	Benzoic Acid
Tar	Thymol
Phenol	Oil of Cinnamon

in the practice of dermatology. Indeed some of the members of this group probably affect a major percentage of the population of the United States. It may be said at the very outset that this fact accounts for the numerous remedies employed in the treatment of these skin conditions and also for the vast number of "patent medicines" offered to an innocent public. The credulity of the physician is similarly attracted.

The parasitic diseases affecting man are best grouped into those caused by (a) vegetable parasites, the dermatophytes which belong primarily to the group of mucorinae or fungi imperfecti and (b) animal parasites, including insects, acari and worms. While destruction of the parasite is the objective in the treatment of both, there are material differences between these two groups and each shall be considered separately.

VEGETABLE PARASITES

At least two fundamental considerations are to be considered before the treatment of this group of diseases can be properly undertaken. The first is the manner of the action of the parasiticides, here better called fungicides, and the second is the response of the individual to his infection.

Strictly speaking, the term fungicide is largely a misnomer. Numerous *in vitro* experiments belie the fungicidal power of most of the remedies listed; some of them even lacking fungistatic powers in high concentrations. Chrysarobin, pyrogallol, sulfur and sodium thiosulfate will not restrain growth of fungi in concentrations of 1:10, salicylic and benzoic acids possess fungistatic properties only in dilutions of 1:50 and 1:40 respectively, but the combination of salicylic and benzoic acids, which forms the basis of the most commonly used antiparasitic ointment, namely, Whitfield's ointment, possesses fungistatic and fungicidal properties *in vitro* even in high dilutions. Iodine, phenol, betanaphthol and mercury bichloride are fungistatic in high dilutions and fungicidal in considerably stronger concentrations. Resorcinol, a very useful member of this group, is fungistatic in concentrations of 1:200 but is not fungicidal. Thymol and certain volatile oils such as the oil of cinnamon and the oil of clove are highly fungicidal even in low concentrations.

Clinically, there can be no question of the efficacy of these remedies. In the superficial dermatomycoses clinical cure, with negative microscopic and cultural examinations, is easily obtained as a rule even with those drugs which are mildly fungistatic *in vitro*. An explanation of the action of these remedies must therefore be sought on other than fungicidal grounds.

These clinically active remedies possess two common qualities in varying degrees: (1) they cause exfoliation of the upper layers of the skin and (2) they produce hyperemia when massaged into the skin. In addition almost all of them are reducing agents. As reducing agents they may cause destruction of fungi aerobic organisms, by depriving them of the oxygen so necessary to life. Exfoliation is produced either by a desiccant action such as that of resorcinol, in which the upper layers dry up and are cast off, or by keratolytic action such as that of salicylic acid, which causes swelling of the horny layer, which finally splits into scales and is exfoliated. In the superficial dermatomycoses the fungi living in the stratum corneum are thus cast off with the scales and clinical cure results without actual destruction of the fungi. Histologic examination of normal skin treated with ointments containing these fungicides shows vascular dilatation and evidence of inflammation, even though the latter may not be clinically manifest. This artificially induced inflammatory reaction may play a role similar to that of the natural inflammatory reactions, following infection with certain members of the ringworm group, in bringing about the death of the parasite. The latter consideration leads to the second of the two fundamental considerations, namely, the reaction of the host to the parasite.

The group of fungi calls forth responses in the human organism which place them immunologically with the bacterial group which produces what is designated as the hypersensitivity of infection. In this bacterial group the tubercle bacillus is the best known and most studied example. This group also includes *Bacillus mallei*, *Bacillus typhosus* and *Brucella abortus*.

Trichophyton, an extract prepared from certain fungi has been as helpful in advancing our knowledge concerning the dermatomycoses as has been tuberculin in the study of tuberculosis, and many analogies exist between the two. The most important of these are that the reaction is specific, is positive in a great percentage of adult people (in the United States) and therefore possesses only limited diagnostic value; is of the delayed type and is negative in most infants even when given

in large doses. The reaction can be elicited many years after infection and this state of altered reactivity probably lasts during the lifetime of the individual.

The length of time necessary for the development of the hypersensitive state, that is, the incubation period, varies with the individual and with the type of infection. The superficial dermatomycoses may call forth very little clinical response, and the trichophyton reaction may be negative even if the eruption has persisted for a long time. In the deep, severe, acutely inflammatory, kerion type of infection on the scalp, or in the bearded region, the reaction becomes positive at the end of from ten to fourteen days and the state of hypersensitivity that is developed is sufficient to destroy the fungi and permit the infection to go on to spontaneous healing.

The secondary lesions arising at a distance from the original focus, which on direct microscopic and cultural examination are usually found to be free from fungi, have their analogy in the tuberculids and are variously termed microsporids, epidermophytids and trichophytids, depending on the nature of the organism producing the infection at the source. The "ids" in the very acute infections, such as those of the scalp and beard go on to spontaneous healing within a relatively short period. In the case of the mycotic infections of the feet however the "id," which is almost always located on the hands and fingers, is apt to run a prolonged recurrent, chronic course, and is also apt to be more recalcitrant to treatment than the original focus.

The foregoing, in a general way, are fundamental considerations which form a necessary background for the proper therapeutic approach to the dermatomycoses. The specific remedies that have been found most useful are best considered by a discussion of the separate disease entities.

RINGWORM INFECTION

The most important member of the group, since it assumes major importance from the standpoint of incidence alone, is the ringworm infection occurring on the hands and feet, the so-called athlete's foot, dermatophytosis of the hands and feet. This disease has definitely been on the increase in recent years, since people have become more sport minded and have been exposed to the infection at golf clubs, beaches, gymnasiums and swimming pools. Dermatophytosis is looked on and classified with the superficial dermatomycoses.

There are primarily three clinical types which, very briefly, are described as follows:

- 1 The interdigital variety, with scaling between the toes varying from the mild grade to the severely macerated, white soggy epidermis, accompanied by fissuring, swelling of the toes, secondary dermatitis and pyogenic infection of the contiguous skin surfaces.

- 2 The acutely vesicular and vesiculobullous type, which usually appears on the sole of the foot and extends along the arch on to the dorsum of the foot. The vesicles are situated on an erythematous base, they rupture or become desiccated leaving crusted and finally superficial erythematous areas surrounded by a scaly collarette.

- 3 The squamous or hyperkeratotic type, which favors the sole of the foot, the arch and the region of the ankle. The lesion is usually well circumscribed rounded dry, scaly and erythematous.

The interdigital type of infection usually accompanies the other two varieties. Pruritus is the most important subjective symptom. It may be mild, very severe or at times surprisingly absent. Hyperhidrosis is frequently present. Secondary infection may take place, producing lymphangitis and adenitis of the inguinal glands which may even go on to suppuration.

Involvement of the nails is manifested by their characteristic dull, lusterless, opaque appearance. Infection may produce deformity of the nail plate, the porcelain-colored streaks of leukonychia trichophytica or separation of the nail plate by an underlying hyperkeratosis.

There appears to be a widespread general impression that ringworm of the feet is so recalcitrant to treatment as to be considered incurable.

PRESCRIPTION 1—For Ringworm

R	Iodine	Gm. or Cc.
	Salicylic Acid	12
	Benzoic Acid	aa 36
	Alcohol 90 per cent q s	ad 1200

PRESCRIPTION 2—For Ringworm

R	Salicylic Acid	Gm. or Cc.
	Resorcinol	60
	Alcohol 90 per cent q s	ad 1200

PRESCRIPTION 3—For Ringworm

R	Thymol	Gm. or Cc.
	Oil of Cinnamon	aa 20
	Alcohol 90 per cent q s.	ad 1200

PRESCRIPTION 4—For Ringworm

R	Thymol	Gm. or Cc.
	Salicylic Acid	03
	Alcohol 80 per cent	10
		300

PRESCRIPTION 5—Whitfield's Ointment (Original Formula)

R	Benzoic Acid	grs xxv
	Salicylic Acid	grs xv
	Paraffin mol	5 II
	Ol cocois nucis	ad 3 I

PRESCRIPTION 6—Whitfield's Ointment (N F)

R	Benzoic Acid	Gm. or Cc.
	Salicylic Acid	120
	Wool Fat	60
	White Petrolatum q s.	50
		ad 1000

PRESCRIPTION 7—Ammoniated Mercury Ointment U S P

R	Ammoniated Mercury	Gm. or Cc.
	Wool Fat	100
	White Wax	50
	White Petrolatum	50
		800

PRESCRIPTION 8—Sulfur Ointment, U S P

R	Precipitated Sulfur	Gm. or Cc.
	Wool Fat	150
	Yellow Wax	50
	White Petrolatum q s.	50
		ad 1000

PRESCRIPTION 9—Chrysarobin Ointment, U S P

R	Chrysarobin	Gm. or Cc.
	Wool Fat	60
	Yellow Wax	50
	Chloroform	50
	Liquid Petrolatum	40
	Petrolatum q s	60
		ad 1000

PRESCRIPTION 10—Dusting Powder

R	Thymol	Gm. or Cc.
	Boric Acid	12
	Zinc Oxide	200
	Talc	
	Zinc Stearate	aa ad 600
Sig	Apply between toes each morning and after bath	

PRESCRIPTION 11—Dusting Powder

R	Sodium Thiosulfate	Gm. or Cc.
	Thymol Iodide	
	Boric Acid	aa 100
	Lycopodium	
	Talcum	aa ad 600
Sig	Apply between toes each morning and after bath	

The choice of the proper remedy diligently applied and continued in decreased concentrations long after the last vestiges of the disease have disappeared will serve to cure almost all cases. Diligence and persistence are the prerequisites of successful treatment. In the recurrent case treatment must be instituted with the appearance of the first signs of recurrence, usually with the approach of warm weather.

For the macerated, soggy, interdigital infection and for the dyshidrotic variety, alcoholic lotions are most suitable, for the hyperkeratotic variety, ointments are most effective.

In prescriptions 1 to 11 are given time-tried, time-honored and most useful remedies. These stand high in the list of eczematogenous substances and the possibility of sensitization to one or another of the ingredients, with an ensuing dermatitis, must always be kept in mind. The patient should be warned against continuing with the use of the remedy in case of irritation. It is most advisable to start with one-half the strength of the active ingredients as listed and gradually increase to full strength.

The 10 per cent solution of silver nitrate, so popular a decade or two ago, seems to have lost face and unfortunately so, since in the interdigital, macerated, fissured type infection it remains one of the most effective remedies.

The useful adjuvant to the various active medications listed, in every form of infection, is the hot potassium permanganate solution foot bath, about 10 grains (0.65 Gm) to the basin of hot water, the feet being soaked for one-half hour daily. In the very acute and very severe processes that incapacitate the individual and make walking impossible, soaks with potassium permanganate 1:2,000 or with Burow's Solution diluted 1:15 for three or four hours daily or continuous wet dressings, with these solutions, give the greatest relief and the most rapid objective improvement.

Unless fungi can be cultivated from the lesions on the hands they are to be considered as dermatophytids and should be treated with soothing, keratoplastic and mildly stimulating remedies. The choice of the remedial agent will depend on the clinical appearance, but antiparasitic treatment is not indicated.

For prophylaxis of ringworm of the feet, solutions of from 0.5 to 1 per cent of sodium hypochlorite are used in all adequately equipped gymnasiums, clubs and schools. Statistical studies show that the incidence of ringworm infection in these places has been materially reduced. Its use is recommended. It need hardly be added that walking barefooted is at all times to be avoided.

An approach to the treatment of ringworm of the scalp requires cultural studies and the mycologic classification of the parasite in every case. Ringworm of the scalp is caused by the microsporon and trichophyton groups of fungi, including both the human-pathogenic and animal-pathogenic varieties. The prognosis as to cure, by the use of topical remedies alone, depends largely on whether or not the fungus is of the animal variety, since the lesions in patients infected with an animal type of ringworm tend to go on to spontaneous healing. The animal type of infection is therefore amenable to treatment with the fungicides listed later.

Infections with the human variety of parasite are more resistant to topical agents even if used over a period of many months. In order to effect a rapid cure and to prevent the inconveniences associated with the isolation of children, recourse must therefore be had, in most instances, to epilation with x-rays. In children approaching puberty, the treatment should be conservative and consist only of the application of the milder antiparasitics, since spontaneous cure takes place at that time. (The dangers of internally administered depilating drugs, such as thallium acetate, are too great to permit their general employment.)

Repeated mycologic examinations of hair and scales and, whenever possible, examination under a Wood's filter light are necessary during the course of treatment. The patient must not be discharged from observation until repeated examinations have proved negative.

The clinical appearance of ringworm of the scalp is varied but can be roughly divided into several groups. The most common in the United States is the dusty appearing, gray, finely scaly variety with oval or rounded patches, in which the hairs are broken off, from 2 to 3 mm in length, lusterless and lifeless in appearance. This variety is usually caused by *Microsporon Audouini*. The disseminated form, with more numerous, smaller and more irregular patches, has large scales, heaped up and adherent, in which the hairs are broken off or matted between the scales. There is also a pustular variety most often produced by the ectothrix type of trichophyton. The inflammatory and suppurative processes may be mild or may be so severe as to produce large, boggy swellings with draining sinuses. This variety, known as *kerion celsi*, heals spontaneously and requires only mild antiseptic wet dressings and soothing remedies.

The practical therapeutic procedures consist first in isolation of the child from other children so as to prevent the transmission of the disease. Adults can be considered to be immune, although occasional adult infection does occur. The hair is to be cut short and kept short, washed with tincture of green soap daily or every other day, and the infected hairs are to be removed with epilation forceps, a few dozen at a time. A washable cap is to be worn at all times until the condition is cured. The following remedies and methods of treatment are suggested:

1 Ten per cent Iodine crystals in anhydrous wool fat. This is very effective and should be applied with a soft tooth brush morning and night. As soon as the reaction becomes severe, treatment is to be suspended for several days and then resumed.

2 Two per cent Tincture of Iodine, dabbed on liberally morning and night.

3 The preparation given in prescription 12.

PRESCRIPTION 12—For Ringworm of the Scalp

	Gm	or	Cc
R Precipitated Sulfur	60		
Salicylic Acid	30		
Castor Oil	60		
Petrolatum q s.	ad	600	

Sig Massage in thoroughly morning and night

PRESCRIPTION 13—For Ringworm of the Scalp

	Gm	or	Cc
R Pyrogallol	50		
Salicylic Acid	50		
Castor Oil	100		
Petrolatum q s	ad	500	

4 The preparation given in prescription 13.

5 Chrysarobin may be substituted for pyrogallol in prescription 13, but precautions must be taken to avoid the annoying conjunctivitis produced by chrysarobin when coming into contact with the eyes. The areas may be covered with zinc oxide adhesive plaster or with collodion.

6 The preparation given in prescription 14.

PRESCRIPTION 14—For Ringworm of the Scalp

R Ammoniated Mercury	5	10 per cent
Salicylic Acid	3	5 per cent
Benzoinated Lard q s		

Irritants such as croton oil, oil of clove and oil of turpentine are used in the superficial variety in an attempt to induce suppuration, thereby converting the superficial into the kerion type. The use of these remedies is not recommended, since they will often produce pronounced scarring. This is not justifiable in a condition that can be treated by other, more satisfactory means.

The principles governing the treatment of tinea barbae are essentially the same as those of tinea of the scalp. Tinea of the bearded region in this country is usually of animal origin and the eruption is of the acute suppurative nodular variety, with boggy swellings and draining sinuses. The infection often goes on to spontaneous cure in a period of about six to twelve weeks. These cases require nothing more than mild antiseptic remedies such as wet dressings of 1:5,000 mercury bichloride and removal of the loose, diseased hairs, followed by the application of an ointment containing 5 per cent ammoniated mercury (U S P ointment mixed with equal parts of petrolatum). The less inflammatory, nonsuppurating type requires more strenuous treatment with the stronger ointments listed, x-ray epilation, or continuous epilation with forceps.

Tinea favosa, or favus, caused by the achlorion group of fungi, is a disease that is quite common in central Europe and is only rarely encountered in this country. It may occur at any age and may attack the scalp, the nails or the glabrous skin. On the skin the eruption is characterized by the pathognomonic sulfur yellow cups, scutula, which may be isolated and few or in juxtaposition, forming sheets covering large areas. It is easily cured by removal of the cups and by daily paintings with tincture of iodine diluted two or three times with alcohol, or with the milder antiparasitic ointments.

Besides the form in which one finds the typical yellow cups traversed by hair, lusterless and lifeless in its lower portions, favus is also present on the scalp in a pityriasisiform and an impetiginous form. In the former, erythematous patches varying in size and number are distributed throughout the scalp covered with adherent, grayish scales. In the latter, one finds yellowish crusts. Microscopic examination of hair and crusts will establish the diagnosis.

On the scalp the lesions are extremely resistant to treatment and require continued and diligent application of remedies over a long period. The treatment is essentially the same as that of ringworm of the scalp, namely, the use of antiparasitic remedies and epilation. Good results are achieved with persistent treatment, and progress of the disease may be arrested. Some cases remain obdurate for a lifetime, others go on to spontaneous healing when destruction of the follicles leads to atrophy and permanent alopecia.

Tinea circinata is a superficial form common on the glabrous skin of adults and children, which may be caused by various fungi of both human and animal varieties. The lesions are circinate, distinctly outlined spots with clearing centers and with an unbroken erythematousquamous border, which advances peripherally, is frequently vesicular and gives rise to lesions that may reach the size of a palm. A single lesion or

PRESCRIPTION 15—For Tinea Circinata

lesions in large numbers may be present. The exposed surfaces of the body are most often involved. In children the scalp must be carefully examined and observed for a time after the body lesions have been cured. Treatment consists in painting the lesions daily with a 2 per cent tincture of iodine or daily application of the ointment given in prescription 15. An effort should be made to determine the source, in order to prevent further infection.

Tinea cruris, the old *eczema marginatum* of Hebra, is an erythematous superficial, scaly eruption in the crural region, which extends downward on the inner aspects of the thighs, sometimes extending upward to the pubic region and posteriorly to the buttocks. The eruption is well defined, sharply margined, with a definitely raised border which is at times vesicular. *Tinea cruris* responds readily to mild antiparasitic remedies and recurrence takes place only if treatment is discontinued too soon. The most pleasant method of treatment consists in the application of a shake lotion (prescription 16) painted on with a brush

morning and night. Cases resistant to this treatment and requiring the addition of 5 per cent precipitated sulfur are rare.

Tinea versicolor, caused by *Microsporon furfur*, with its smooth or slightly scaly, fawn colored patches of varying size and shape, is found on the chest and back but may also spread to other areas. The eruption causes no symptoms, it is harmless and the individual presents himself for treatment primarily for cosmetic reasons. The eruption is found more often in those who have a tendency to perspire freely and therefore occurs frequently in the tuberculous. Daily baths using soap freely followed by vigorous application of a 10 per cent aqueous solution of sodium thiosulfate will cause the disappearance of the eruption within a week. Infection in the pubic region is often overlooked. It is wise to treat this area in a routine manner in all patients. Treatment must be persisted in for at least several weeks to avoid recurrence. The underclothes must be boiled.

Erythrasma, caused by *Microsporon minutissimum* affects the same areas as *tinea cruris* and is sometimes confused with it. Not infrequently erythrasma also affects the axillae. In contradistinction, erythrasma is more brownish red, is not elevated and has no raised vesicular border. The treatment is the same as that of *tinea cruris*.

MONILIA

The mycoses caused by yeastlike organisms have a striking resemblance to those caused by the ringworm group. They produce similar clinical pictures and affect the same areas. Mycologic studies are often necessary in order to determine whether one is dealing with ringworm or with yeast infections. Yet these organisms are not immunologically related. Patients with pure monilia infections react strongly to *oidiomyxin*, an extract produced from the monilia group of organisms while their reaction to *trichophytin* is negative or, if positive is based on previous infection with ringworm organisms. Positive passive transfer tests may be elicited by various members of the ringworm group with serum from an individual urticarially hypersensitive to *trichophytin* whereas the members of the yeastlike group will give negative results with this serum.

The great folds and clefts of the body are the sites of predilection for infection with monilia and so one finds that the interdigital spaces, the crural and anal regions, the vulva, the areas beneath the breasts in women and the abdominal folds in the obese, are the sites most often involved. The characteristic picture

in one of these large folds shows a grayish white sodden macerated band of variable width, usually narrow, running along the cleft, with an erythematous moist shiny area extending beyond the grayish border. Outlying satellite pinhead sized, papular, vesicular and pustular lesions are almost always present.

These infections occur more frequently in diabetic patients and in the obese. It is wise to study all these patients from this point of view and, whenever deemed advisable to reduce the carbohydrate intake. Wet dressings with a 0.25 per cent silver nitrate solution for from twenty-four to forty-eight hours followed by the use of the 4 per cent resorcinol lotion (prescription 16) will often be sufficient to effect a cure. An attempt must be made to keep the parts dry by the liberal use of dusting powder in these areas, and an attempt must also be made to prevent the skin surfaces from coming directly into contact with each other. Interdigital infection with monilia is very common. The clinical appearance and the treatment is the same as that of interdigital ringworm.

Erosio interdigitalis blastomycetica occurs chiefly in those keeping their hands immersed in water a great deal and therefore in housewives and persons employed in occupations such as canning and "soda jerking". The eruption is almost always located in the web between the middle and ring fingers extending on the sides of the fingers for a variable distance is shiny, moist, erythematous and at times covered with a central grayish sodden epidermis. Prophylaxis is the first principle of treatment. The hands must be protected against the effects of moisture by the use of rubber gloves or by abstaining from those processes requiring immersion of the hands. The eruption can readily be cured by painting a 5 per cent solution of silver nitrate on the affected parts morning and night, or by the daily application of a 2 per cent tincture of iodine solution. Sulfur Ointment U S P or Ammoniated Mercury Ointment, U S P are equally efficacious. These ointments should first be used in half strength, i. e., by mixing with equal parts of petrolatum or some other ointment base, and then, if necessary, used full strength.

Not infrequently changes in the nails and paronychia accompany the interdigital infection. The nails become lusterless, opaque and thickened, with transverse or longitudinal ridges. The eponychium becomes erythematous and edematous. These patients cannot be cured unless they abstain from the use of water on the skin. Locally superficial unfiltered fractional doses of X-rays

PRESCRIPTION 17—Ointment for *Perleche*

combined with the use of half strength Sulfur Ointment U S P or half strength Ammoniated Mercury Ointment U S P, gives the best results.

Erosio interdigitalis blastomycetica, paronychia and *perleche* are so frequently associated as to be considered a triad. It must not be accepted that all cases of *perleche* are due to monilia infection since cultural examination may show only streptococci and staphylococci. *Perleche* manifests itself by fissures at the corners of the mouth at times covered with a whitish pellicle on an erythematous base. In severe cases of long standing the mucous membrane of the cheek becomes involved. Pain may or may not be present depending on the depth and extent of the fissuring. Treatment consists in the daily application of a 2 per cent aqueous

solution of silver nitrate a 1 per cent aqueous solution of copper sulfate or of the ointment given in prescription 17

The use of wet dressings or the continuous water bath may give rise to a very superficial vesicular and

pustular eruption, often covering large body areas. This is referred to as bath mycosis. Treatment necessitates the discontinuance of the water bath or the wet dressing and the application of dusting powder, such as the one given in prescription 18, or painting liberally three times daily until cured with the lotion given in prescription 19.

ANIMAL PARASITES

The treatment of animal parasitic diseases offers a problem much less difficult. Here one is dealing with animal life on the skin surface or in the horny layer of the epidermis or on the underwear. In rare instances the parasite is to be found below the epidermis. The parasite either is accessible or can be made more accessible by solvents of the horny layer and it is readily destroyed by even small concentrations of the parasitocides. The primary consideration should therefore be to do no harm, since the remedies employed are, in high concentrations irritants, and also since the number of people who have a heightened susceptibility to these remedies is not inconsiderable.

As a group, the animal parasites account for from 8 to 10 per cent of patients encountered in clinic practice. The percentage in private practice is much smaller since this group of diseases occurs more commonly in the poorer classes, in people who are more subjected to crowding and people whose personal hygiene is both poor and apt to be neglected. There are only two diseases in this group which are of significance because of their frequency, namely, pediculosis and scabies.

PEDICULOSIS

Three kinds of lice are parasitic to man: the head louse, the body louse and the pubic louse.

Head lice, causing pediculosis capitis, are found in childhood but at times also affect the adult. The lice cause severe itching and scratching, which may give rise to secondary excoriations, impetiginized lesions, folliculitis and even abscess of the scalp. Secondary infection may be accompanied by swelling of the glands of the neck. A large number of ova attached by a chitinous membrane to the hair, are distributed throughout the scalp. The diagnosis is simple indeed.

The case with which the parasite can be destroyed is borne out by the method of treatment used at the Saint Louis Hospital in Paris in the severe cases in which the head teems with pediculi, namely, the application of a thick layer of petrolatum over the entire scalp which is then bandaged overnight. The parasites are destroyed by suffocation. Pediculi may be destroyed by the application of an aqueous solution of mercury bichloride 1:5000 or a 2 per cent betanaphthol ointment

a 5 per cent sulfur ointment or a 10 per cent salicylic acid ointment. The last mentioned possesses the added advantage of loosening the ova (nits) and softening the crusts so often found in lousiness of the scalp. The nits are best removed with a fine comb dipped in hot vinegar which dissolves the chitinous membrane attaching the nit to the hair. The danger accompanying the use of the easily ignitable crude petroleum cap, which enjoys a certain modicum of popularity, should be sufficient to cast this form of treatment into the limbo of discarded procedures.

Body lice, causing pediculosis corporis inhabit the clothing coming into contact with the skin and are characteristically found in the seams of the under-clothing. Sterilization of the clothes and personal cleanliness will suffice to effect a cure.

Pubic lice, causing pediculosis pubis, are not confined to the pubic region but will be found also on the thighs and in the perianal region, buttocks, axillae, eyebrows, eyelids and beard. They will not live in the scalp. Mercurial ointment, almost a classic form of treatment is mentioned only to be condemned. The use of an ointment of such strength for the destruction of pediculi is unwarranted. The dermatitis and also the stomatitis to which it may give rise, even after a single application, is more serious and more annoying than is the pediculosis. Such strenuous measures are unnecessary. An ointment such as the one given in prescription 20 or the U. S. P. Ammoniated Mercury

Glycerin q s.	ad 1000

the prescriptions 21 and 22. The mercury bichloride solution is applied for three or four nights in succession and then less frequently, every three to seven days, for from two to three weeks.

The ova are removed with xylene or with hot vinegar, as mentioned under pediculosis capitis. A cure in this condition is not to be expected in less than a week, in those with a profuse growth of hair on the abdomen and chest, cure may be delayed two weeks or even longer. Daily and diligent application of remedies is essential. Shaving of the affected parts will hasten the cure, but the discomfort attendant on shaving the affected areas may be obviated by the conscientious application of the remedies.

Scabies is a contagious dermatosis caused by an acarid, *Sarcoptes scabiei*, in which the female of the species burrows into the skin, within the horny layer usually at some favored site, depositing ova and excrement along this tunnel. The ova hatch in from four to six days and are ready to repeat the cycle. The male of the *Acarus* family lives on the skin surface and is easily disposed of.

The eruption is symmetrical and has a characteristic distribution affecting primarily the webs of the fingers, the flexor surfaces of the wrists, the elbows, the anterior axillary fold, the ankles and the buttocks, in women, the breasts and nipples, in men, the penis, and in children the palms and soles. Needless to say, the lesions may appear in other areas but the eruption is characteristically absent above the clavicular level. In the unhygienic the eruption is apt to be characteristic, severe, with numerous vesicles, with secondary scabietic eczema due to scratching and with secondary infected lesions. In the cleanly it may be so mild as to offer difficulty in diagnosis. However, the contagious character of the eruption, the nocturnal pruritus, and finally the demonstration of the acarus help in establishing the diagnosis even in these questionable cases.

Destruction of the parasites and ova will cure the itch. Sulfur is the time-honored remedy and the remedy of choice. The parasiticidal action of sulfur is, in all probability, due to the formation of hydrogen sulfide on the skin, which, even in low concentration, is fatal to animal life. The patient is instructed to take a warm bath and to wash thoroughly with soap and water for at least one-half hour. Sulfur ointment, U. S. P., one-half strength, is then massaged gently over the body below the clavicular level. Application of the salve, without bathing, is repeated on the two succeeding nights, and on the fourth night the patient is instructed to bathe again. During this course of treatment the same bed linen and underclothing are used. At the end of the course the linen and clothing are both changed. Sterilization of the underclothing and bed linen is essential. Recurrence is to be attributed to reinfection, in which both improper care of the clothing and the original source of contact play no small part. For obvious reasons, all members of a family who are infected are to be treated at the same time. The patient is to be observed again after a period of several days, and if he is not symptom free and if the physician is convinced that the pruritus is not due to irritation from sulfur, and also that the scratching is not due to habit alone, he is to undergo another course of treatment. Two courses of treatment properly carried out should be sufficient to cure scabies.

In the more severe type of case seen in clinic practice, stronger ointments are used. The addition of

PRESCRIPTION 23—Compound Ointment of Sulfur, N. F.

soaps and alkalis, such as potassium carbonate, makes for better penetrating power into the burrow. The best known of these are prescriptions 23 and 24.

Another convenient and effective method used in the treatment of scabies in children is the one advocated by Sherwell. Before retiring, the child's body is gently rubbed with flowers of sulfur and then the child is permitted to sleep in a bed that has been sprinkled with the flowers of sulfur. The duration of treatment is one week. Dermatitis from this form of treatment is rare.

There are many other remedies used in the treatment of scabies, but these will be mentioned only

briefly. Peruvian Balsam from 5 to 15 per cent in ointment form or mixed with equal parts of alcohol is useful. Styran, another balsamic, may also be used in ointment form or as in prescription 25.

PRESCRIPTION 25—Styran Ointment

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING PRELIMINARY REPORT
PAUL NICHOLAS LEECH, Secretary

REPORT ON THE PRESENT STATUS OF TETRACHLORETHYLENE

Tetrachlorethylene is an unsaturated halogenated aliphatic hydrocarbon with specific gravity of 1.60, a boiling point of 121°C and a chlorine content of 85.5 per cent. It has become an official drug by its admission to the new National Formulary. It is stated to contain not less than 99 per cent and not more than 99.5 per cent of CCl_2 , CCl_2 —the remainder consisting of alcohol. It is claimed to be a useful agent in the treatment of hookworm infestation as evidenced by the many clinical as well as experimental reports which have appeared in medical literature.

Garrison,¹ writing on the use of tetrachlorethylene in the treatment of hookworm in children, noted the following percentage of infestations: 26 per cent (estimated)² of Southern school children, 15 per cent of a certain series of 5,000 hospital admissions, 22 per cent of the 121,388 specimens examined by nine state departments of health in 1930, 50 per cent of the individuals in a Mississippi CCC camp, and 51 per cent of certain groups of Mississippi school children.

Lamson, Brown and Ward³ reviewed 500 references to the treatment of hookworm and *Ascaris*, on which a total of 300 different anthelmintics were employed. They studied an additional 300 agents against *Ascaris* and pointed out that all agents in common use (except tetrachlorethylene and hexylresorcinol) were well known poisons.

The high efficiency of chloroform in the treatment of infestations led Hall to use carbon tetrachloride in animals and it was later used extensively in man. Hall and Shillinger⁴ studied other related compounds including ethylene dichloride and tetrachlorethylene. They employed the latter agent in twenty-three infested dogs and found it to be an efficient anthelmintic. Christiansen and Lynch⁵ concluded from their comparative studies of tetrachlorethylene and hexylresorcinol in animals that although there was only mild fatty infiltration of the liver and no kidney involvement, there was (post mortem) spongy shriveled and inflamed intestines. They claimed that the heart and respiration were both depressed but they used 1.2 and 3 cc. of the drug in these dogs. Lamson and his co-workers did not class tetrachlorethylene with carbon tetrachloride because the guanidine content of the blood did not change as with the latter.⁶ This is especially advantageous in treating infested patients having calcium deficiency. Schlingman and Grubitz⁶

2 Stiles, C. W. Address before the Southern Medical Association, Nov. 14, 1933.
3 Lamson, P. D., Brown, H. W., and Ward, Charlotte B. Anthelmintics. J. A. M. A. 99:292 (July 23) 1932.
4 Hall, A. C., and Shillinger, J. E. A New Anthelmintic. Am. J. Trop. Hyg. 5:229 (May) 1925.
5 Christiansen, B. V., and Lynch, H. J. Effect of Anthelmintics on the Host. I. Tetrachlorethylene. II. Hexylresorcinol. J. Pharmacol. & Exper. Therap. 48:311 (July) 1933.
6 Schlingman and Grubitz. Toxicity of Tetrachlorethylene. J. A. M. A. 74:189 (May) 1927.

found very slight changes, principally in the liver. Mapleston and Chopra⁷ found it much less toxic than carbon tetrachloride and concluded from their experiments that it caused no damage to the organs of otherwise healthy animals (cats) in therapeutic doses. Lamson and his co-workers⁸ pointed out that little if any [?] was absorbed from the dog's intestinal tract in the absence of fat. If fat was present, however, it produced hypnotic symptoms, even death.

Noting these experiments, Hall and Shillinger⁴ and Lamson and his co-workers⁸ were of the opinion that since it is less toxic than carbon tetrachloride, and as efficient as the latter, its clinical use would not be contraindicated.

Garrison¹ compared tetrachlorethylene with oil of chenopodium and carbon tetrachloride in 627 children and his results were much more satisfactory than with the latter two agents. Schapiro and Stoll⁹ found that 3 cc reduced the egg count 81 per cent and 2 cc reduced it 77 per cent, as compared with 47 per cent reduction using 15 cc of oil of chenopodium and 24 per cent with less than 1 cc of the oil. Smith¹⁰ used 1 cc. in 276 school children and claimed an effectiveness of 90.5 per cent.⁹ Garin, Roussel and Gonthier¹¹ used 3, 4 and 5 Gm (1 Gm at hourly intervals) doses on successive days in 371 treatments resulting in 332 expulsions, most of which occurred after one treatment. Mapleston and Mukerji¹² reported it not superior to carbon tetrachloride except that it might be less toxic. Later they¹³ found it satisfactory, in combination with oil of chenopodium and magnesium sulfate. In a series of fifty cases, using Lane's centrifuge method (considering ordinary counts unreliable), they reported thirty-one negative ten days after the first treatment and twelve more after a second treatment. Garrison¹ noted that negative stools were obtained in 49 per cent of the cases in the CCC camp mentioned after 2 cc. of tetrachlorethylene had been given. Kendrick¹⁴ concluded from his work that it was superior against *Ancylostoma* in doses of 3 cc (in fifty-nine cases) and 2 cc (in fifty cases). He further noted it inferior to 24 cc. of a 3 to 1 mixture with oil of chenopodium in thirty cases of *Necator* infestation. Soper¹⁵ had previously reported fifteen cases with similar but less favorable results against *Ancylostoma* and far less favorable against *Necator* in comparable work in which carbon tetrachloride was used for control. The same decreasing order of resistance against all these agents is reported by both authors.¹⁶ female *Ancylostoma*, male *Ancylostoma*, male *Necator*, female *Necator*.

Lamson⁸ noted that the use of the older remedies involved a possible risk of death, a fair chance of collapse, an acute nephritis from betanaphthol, disturbance of vision with santonin, deafness from oil of chenopodium, and necrosis of the liver with carbon tetrachloride. He and his co-workers⁸ felt that severe intoxications were much more frequent than reported. They were of the opinion that tetrachlorethylene differed from chloroform and carbon tetrachloride in causing no pathologic or functional change. They stated that they had been assured the product would not break down to phosgene (This factor caused some earlier workers to abandon its use).

Lambert¹⁷ reports 286,486 cases of hookworm disease treated with tetrachlorethylene or carbon tetrachloride either alone or in combination with oil of chenopodium. Early in the series

there were seven deaths—one from oil of chenopodium without purge and six after carbon tetrachloride. Over a period of four years he used tetrachlorethylene in 46,000 cases with no deaths and with fewer toxic symptoms than with other agents. Lamson⁸ felt that the lowered toxicity permitted the use of a less violent cathartic and suggested sodium sulfate in place of the magnesium sulfate. It has been reported¹⁸ that tetrachlorethylene could be given with alcohol and that its toxicity was not affected by alcohol but it would seem preferable to avoid the combination.

The toxic effects (reactions) consist of giddiness, vomiting and drowsiness,¹⁸ although these are supposedly not related to liver effects.¹⁸ The experimental occurrence of cardiac and respiratory depression has not been encountered clinically, no change in rate of either, although there was a slight lowering of blood pressure. Sharp¹⁹ felt that reactions were more frequent in children, while Garrison¹ had little difficulty with his young patients (they were confined to bed during the procedure).

Tetrachlorethylene has been used against other worms with little or no success except in the case of *Trichuris* infections.²⁰

Lambert¹⁷ (after treating 46,000 cases with tetrachlorethylene and over 200,000 cases with other agents) considers it the most satisfactory anthelmintic against hookworm disease. Lamson⁸ reported that it was just as good as any drug or combination of drugs against both *Necator* and *Ancylostoma*. Mapleston and Mukerji¹² considered it superior to carbon tetrachloride and safer than either the latter or oil of chenopodium. Garrison,¹ after using it in children considered it to be satisfactory, most economical, and the best anthelmintic against hookworm.

The Council authorized publication of the foregoing report on the present status of tetrachlorethylene.

In the 1937 edition of *New and Nonofficial Remedies* there will appear a description of tetrachlorethylene with a considered statement of actions and uses.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS CONFORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

ANTIPNEUMOCOCCIC SERUM TYPES I AND II COMBINED (See *New and Nonofficial Remedies*, 1936, p. 374)

Mulford Biological Laboratories, Sharp & Dohme, Philadelphia and Baltimore

Antipneumococcic Serum, Types I and II Combined Mulford—A serum obtained from horses immunized with type I and type II pneumococci and standardized by animal potency tests. It is marketed in packages of one 50 cc. double end vial and in packages of one vial for intravenous injection.

Dosage—From 50 to 100 cc. given intravenously and repeated every six to eight hours until the temperature falls and beneficial effects are evident.

Antipneumococcic Serum, Concentrated (Pneumococcus Antibody Globulin Types I and II) Mulford—A serum obtained by immunizing horses with intravenous injections of type I and type II pneumococci. It is subjected to the usual sterility and safety tests by injection into white mice and guinea pigs. Standardization is effected on the basis both of the mouse protection test and by a specific polysaccharide precipitation test devised by Zozaya, Boyer and Clark (*J. Exper. Med.* October 1930, p. 471). The potency of the product is expressed in terms of the unit described by Felton (*J. Infect. Dis.* September 1925, p. 199; October 1925, p. 309; *THE JOURNAL*, June 14, 1930, p. 1893). Marketed in packages of one 10 cc. syringe containing 10,000 units and in packages of one 20 cc. syringe containing 20,000 units.

Dosage—Initial dose, 10,000 units followed in one hour by a second dose of 20,000 units; the second dose is repeated at intervals of from four to eight hours until the temperature falls and beneficial effects are evident.

MEDICAL TRUANTS

After years of arduous preparation for the practice of medicine, a physician occasionally finds that his principal talent or interest lies elsewhere and he wanders off into other fields of attainment. This has been true throughout the history of medicine. Some illustrious medical truants have thus been donated to science, to literature, to law and to the state. The late Lord Moynihan¹ cited in his recent Linacre lecture some of the better known medical truants—Copernicus graduated in medicine at Cracow, but he is remembered today as the professor of mathematics who published a treatise on the Revolution of the Planets Around the Sun in 1543. Thomas Linacre himself, the first president of the Royal College of Physicians, and physician to a king was more highly esteemed as a scholar than as a physician. The great philosopher John Locke graduated in medicine at Oxford and actually engaged in medical practice. His later years were devoted to philosophy and it was he who equipped the Whigs with their political philosophy for the next century. Berzelius a great chemist was professor of medicine at Stockholm. John Woodward who created the first geological museum, received his medical degree from Cambridge and then distinguished himself as a geologist. Malpighi was physician to the Pope yet he turned to botany and became a pioneer in vegetable microscopic anatomy. The humble doctor's office seems far removed from the Vatican, and yet Dr. Petrus Hispanus actually became Pope John XXI his pontificate extending from Sept. 8, 1276 to May 20, 1277 when he was killed by a roof collapsing in his palace.²

The great botanist Linnaeus held the degree of doctor of medicine from Uppsala. Sir Thomas Hooker graduated in medicine at Glasgow and then went as a physician with the Ross expedition to the antarctic where he studied the flora so intently that six volumes

were required to present his studies. Darwin first propounded his theory of natural selection to Hooker.

Some physicians have given to politics the energy which they first intended for the practice of medicine. The romantic Georges Clemenceau qualified in medicine in 1865, then spent much of his life in politics. He practiced medicine in New York and later in Paris as a specialist in skin diseases, going into politics he became mayor of Montmartre, a member of the chamber of deputies, a senator and finally the most masterful prime minister of France, serving during the hectic World War to earn the title of savior of his country. The first president of the Chinese Republic Sun-Yat-Sen, graduated from the College of Medicine in Hong-Kong in 1892. Joseph Warren of Massachusetts was a popular doctor of medicine, who eventually went into politics, he, with Samuel Adams, did much to arouse the spirit of liberty in Massachusetts. It was Dr. Joseph Warren who sent Paul Revere on his famous ride through Arlington, Concord and Lexington, and when news of battle came he rode to the scene of action and later was killed at the battle of Bunker Hill. Leonard Wood, who graduated at Harvard Medical School in 1884, entered the army medical corps and finally became one of the greatest colonial administrators America has produced.

John Keats is a perfect example of the medical truant. His interest was elsewhere even during his student days, when he wrote to a friend:

The other day during the lecture there came a sunbeam into the room, and with it a whole troop of creatures floating in the ray, and I was off with them to Oberon and fairyland.

Keats became apprenticed to a surgeon and then, though poor abandoned medicine for literature. Sir Ronald Ross was a poet but his abiding fame remains in his monumental work on the transmission of malaria. S. Weir Mitchell the leading American neurologist of his time, has a place in the world of letters near Goldsmith and Holmes not far below Scott and Lamb.³ The tone of his books, said Wister, 'is a lesson and a tonic for an age that is sick and weak with literary perversities.' Mitchell was the first to describe causalgia, erythromelalgia and postparalytic chorea and, with William Thompson was the first to emphasize the importance of evestram as the cause of headache. When the beloved Dr. Oliver Wendell Holmes was appointed professor of anatomy and physiology at Harvard University, he had so many duties that he said "I occupy not a chair but a whole settee." Holmes did not desert medicine, he made medicine the companion of literature, Lord Moynihan said of his work on puerperal fever published in 1843 that it is "one of the greatest essays ever written in the history of medicine." The German poet Schiller was a graduate in medicine. Goethe also a great German poet and a biologist, was one of the pioneers of evolution.

tion He was the first to use the term 'morphology', and he discovered the intermaxillary bone Goldsmith, the beloved poet, was a medical graduate, although some writers doubt his right to describe himself as doctor Goldsmith was for a time physician to the poor at Bankside He obtained a medical appointment with the East India Company, which later revoked it He presented himself for examination for hospital physician but again was rejected Turning then to literature he found immortality, and his *Vicar of Wakefield* will be read as long as the language lasts

Edward Jenner, the discoverer of vaccination, was in a minor sense a poet David Livingstone graduated in medicine, then almost immediately embarked to explore Africa Hermann von Helmholtz, the mathematical physicist, was educated to be a surgeon in the Prussian army but spent much of his life as professor of anatomy and physiology and of physics He was the author of the great *Handbook of Physiological Optics*, which Garrison says is a permanent classic He invented the ophthalmoscope, the ophthalmometer and the phacoscope After assuming the chair of physics at the University of Berlin in 1871 he devoted the remainder of his life to the field in which his true genius lay and in which he was equaled, in modern times, only by such men as Lord Kelvin and Clerk Maxwell It was in Helmholtz's laboratory that Hertz discovered the hertzian waves, which later led to wireless telegraphy Helmholtz, however, never forgot that he was a physician "Medicine," he said, with pride, 'was once the intellectual home in which I grew up, and even the emigrant best understands and is best understood by his native land' Helmholtz was also a great lover of music and the most prominent of many German scientists of his time who followed music He not only performed but was the founder⁵ of musical esthetics as a science and the author of the most exhaustive treatise on the physical basis of tonal sensations that has ever been achieved His great work *Tonempfindungen* was published in 1863 Theodore Billroth, the pioneer of visceral surgery and the greatest German surgeon in his time, was the grandson of a famous soprano Beneath his calm exterior was the musician and poet He carried on a lifelong friendship, indeed a sort of musical brotherhood, with the great composer Brahms, the central figure in the famous musical evenings at Billroth's Vienna home Although John Hunter, a great Scotch surgeon, had no liking for music, his wife, Anne Hunter, was a patron of music and wrote the words for Hayden's *Creation*

Lord Moynihan sketched the careers of other medical truants, including Galileo and Sir Thomas Browne, among artists there was Sir Francis Seymour Haden, who was vice president of the Obstetrical Society and founder and first president of the Royal Society of Painter-Etchers Sir Francis produced 250 works of

his own, it is said that as a physician he often made rounds with an etching plate in his pocket The list is long, including also actors, sportsmen and sculptors, and the evolutionary process is still at work It has been especially revealed recently in the annual exhibits of hobbies and the avocations enjoyed by hundreds of physicians

DISTRIBUTION OF CEVITAMIC ACID IN TISSUES

Progress in many branches of science passes through rather definite steps The first period is usually characterized by qualitative discoveries and advances of a qualitative nature This is followed frequently by a period more quantitative in its scope An excellent example of this general tendency is presented by the case of vitamin C The earliest work dealt with the existence of such a substance and its qualitative presence or absence in different foods Subsequently, with the isolation, determination of the chemical structure synthesis, and development of highly sensitive and rather specific methods for its determination, the problem has changed abruptly into a distinctly quantitative phase Here again is seen an orderly progression of study The earlier investigations were of a macroquantitative type, whereas more recent studies have tended to be microquantitative in character Likewise, in the case of the distribution of cevitic acid in tissues, the emphasis has shifted in turn from tissues in general to specific organs and, in the most recent work to a study of the vitamin content of individual cells

Several years ago, experimental studies demonstrated that practically all tissues of the body contain some vitamin C but that in general the largest amount is present in glandular tissue and the least in muscle tissue and stored fat¹ Subsequently it was found that different organs vary considerably in their content of cevitic acid The adrenal, pituitary, corpus luteum and thymus contain the largest amount of the vitamin whereas the pancreas, liver, spleen, testis, ovary, brain thyroid, submaxillary gland and intestinal mucosa contain successively less Somewhat smaller amounts are present in the kidney, lung and heart Similar variations in the vitamin C content of different human organs obtained at necropsy have been reported¹

In a recent series of investigations² the question of the distribution of cevitic acid within certain organs has been studied in an ingenious manner Whole glands—adrenal, pituitary, ovary and thymus—were removed from freshly killed cattle and frozen at -5°C to pre-

vent loss of the vitamin. A small cylindric sample of the frozen tissue was then removed and the specimen was mounted on a freezing microtome and sliced into thin sections, some of which were periodically taken for analysis by a microchemical method, sensitive to ± 0.0001 mg of the vitamin. This procedure permitted a study of restricted portions of the gland and indeed, in certain instances, of the different types of cells themselves. It was observed that the vitamin C content of the tissue taken from the fascicular zone of the adrenal cortex was nearly twice that of the same-sized slices taken from the medulla. In order to determine whether the difference was actual or only apparent because of the presence in the medulla of structures, such as nerves and vascular spaces, containing only small amounts of the vitamin, cell counts were made in the various areas and from these values the cevitamic acid content of the individual parenchymal cells was estimated. The actual amount of the vitamin present in the relatively small fascicular cortical cell was still significantly greater than that present in the larger medullary cell. A similar type of study of the pituitary demonstrated that an exceedingly high concentration of vitamin C was present in the pars intermedia. Indeed, the concentration of the vitamin in this portion of the pituitary, according to the authors, is the highest of any tissue yet recorded, being some 15 times greater than that in the cells of either the pars distalis of the pituitary or the adrenal cortex.

The concentration of cevitamic acid in the corpus luteum and the thymus was likewise determined by the same method and an attempt was made to detect possible changes with age and physiologic activity. The quantity present in the corpus luteum was found to be at a maximum in the fully mature organ, a decrease occurring during the period of involution and atrophy. It is of interest to note that the fluctuations in the vitamin content of the corpus luteum parallel to a striking degree the changes in the amount of the luteal hormone, progesterone, present in the gland. There is some indication, it is pointed out, that this relationship may be more than a casual one. In the case of the thymus, the amount of cevitamic acid in the gland of the calf or the fetus exceeds that present in the glands of cows and bulls. However, the apparent decrease with age was shown to be due to the displacement of active glandular tissue by fat and connective tissue during involution. There was no significant decrease in the concentration of the vitamin in the glandular cells themselves.

Searching studies of this type have more than academic significance. Not only will they yield knowledge of fundamental value in elucidating the question of the function of vitamin C in the animal organism, but now that the chemical properties of cevitamic acid have become known such investigations will point out more clearly the specific function of the organ or cell in question.

SURGICAL EXAMINATIONS AND THE INTERNATIONAL COLLEGE OF SURGEONS

Announcements, now widely circulated to the American medical press, indicate that the International College of Surgeons, discussed in our editorial columns¹ on June 20, is about to conduct examinations for membership and fellowship for those who apply and indicate their willingness to pay \$250 for the purpose. Thus it now becomes possible for a young man who wishes to find out whether or not he is a surgeon to obtain the information from three or more sources. He may submit his credentials and take the examination afforded by the American College of Surgeons, he may undertake a similar process in relationship to the International College of Surgeons, or he may no doubt within the near future apply for examination and certification by the Certifying Board in Surgery, which is in process of formation.

Subsequent to the publication of the current comment already referred to, the International College of Surgeons made available a roster of state regents, specialty regents and fellows, who apparently accepted the nominations given them with the understanding that they would not be requested to invest financially in their honors. There are indications that a considerable number of these "lead horses" subsequently became aware of the extraordinary nature of the organization by which they had been honored and intimated a desire to relinquish the special recognition which had been conferred on them. No doubt they should be free from condemnation in view of the fact that many American and foreign leaders whose names were associated with the prospectus were persons of high repute and distinction in American and foreign surgery, whose names in themselves should be warrant of scientific merit. Nevertheless, some others apparently felt the new organization a suitable substitute specially designed for the benefit of those who have failed to meet the requirements of the well established International Society of Surgery. In the general news columns of this issue of *THE JOURNAL* appears an announcement of the International Society of Surgery with regard to its next meeting in Vienna in September 1938.

What are the difficulties primarily concerned in the promotion of the new International College of Surgeons? As was pointed out in our original current comment, there seems to be no good evidence that such a body will meet any need not already provided for by established organizations. The proposals for an international museum of surgery in Geneva and for international reciprocity, the committee to restrict the publication of unestablished surgical material, the building to be erected and the higher degrees are, to say the least, grandiloquent conceptions. The automatic selection of 300 American surgeons by a self-constituted

¹ The International College of Surgeons—Why? *Current Comment*, J. A. M. A. 100: 2162 (June 20) 1935.

body is in itself no guaranty of competence in those who will pay \$250 for the examination. The International Society of Surgery during thirty-one years has already selected 125 leading American surgeons for 150 places available to American surgeons of established prestige. Is it to be considered that any considerable number of surgeons will care to avail themselves of membership, fellowship, mastership or any of the other distinctions to be conferred by both these organizations? Finally, what can the International College of Surgeons have to offer beyond the prestige already available through the certificate of fellowship in the American College of Surgeons or the certificate to be made available by the new Certifying Board?

To the average American physician it may appear that *THE JOURNAL* is concerning itself unduly in this matter. The problem of multiple medical organizations in various fields is one that has concerned leaders in American medicine for many years. Readers will recall previous editorials in relationship to the American Medical Editors' and Authors' Association. Certainly it is within the province of *THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION* to make American physicians aware of the conditions surrounding any effort or organization which makes a distinct appeal for the funds of American physicians. Those who have contemplated application to the International College of Surgeons for one of the examinations to be offered in various portions of the United States and Canada under the auspices of local regents may well consider the value of the return which they are likely to receive for their investment.

Current Comment

DISTRIBUTION AND HOSTS OF THE HUMAN FLEA

With the recent recognition of sylvatic plague in Montana and Oregon, data on the distribution and host relationships of fleas in these states, particularly those species known to attack man, assume a new and important interest. For this reason, records which show the association of the human flea *Pulex irritans* L. with plague-susceptible native rodents, wild carnivores, game animals and household pets within these states are of particular value. Data of this type have been recently presented by Jellison and Kohls¹ of the United States Public Health Service. The records show particularly that *Pulex irritans* is well established in many parts of Montana. In the search for possible hosts it has been possible definitely to identify *Pulex irritans* obtained from prairie dogs, domestic dogs, coyotes (*Canis latrans*) and deer (*Odocoileus* Sp.). Evidently this flea may occur frequently on coyotes in other Western states, as collections made from this host in Colorado, in Oregon and in California have contained specimens of *Pulex irritans*. These preliminary observations indi-

cate that, in view of the diverse host data and the number of locality records that have been obtained in a relatively brief period, *Pulex irritans* has been a well established species in these regions for some time. Further field studies will undoubtedly increase the list of host animals as well as add extensively to the data regarding additional details of the life history of this parasite.

Medical Economics

THE STUDY OF CONSUMER PURCHASES

A New Survey of Family Expenditures

A new study of consumer purchases now in progress is planned to provide facts concerning medical costs free from propaganda. It is the most comprehensive survey ever made of American family expenditures. It is to include 52,000 families at all income levels and in all occupations.

The actual fact gathering has been divided between two federal government organizations. The U. S. Bureau of Labor Statistics is conducting the survey in urban centers and the U. S. Bureau of Home Economics is surveying agricultural areas. Plans for the study were formulated by a committee of representative economists in cooperation with the National Resources Committee. They follow the lines proposed by the Social Science Research Council in 1929 and suggestions made by the Chamber of Commerce of the United States in 1932.

As a result of this study, it is said, the medical profession will be able to learn the relation of family expenditures for medical care to expenditures for other specific goods and services, how this relationship varies with annual incomes ranging from \$250 to \$10,000 a year and over, how the occupation of the principal wage earner, the size of the family and the amount of the income influence the family's selection among the various types of medical care, how expenditures differ among rural and urban families, whether an urban family with a rural background is more likely to turn to specialists than a city-bred family, or whether the number of members in the family and the amount of the income play a more important part in the selection of medical services.

The detailed information which the 52,000 families are giving will not be lumped together in a mythical "average." The data are being analyzed by geographic areas for thirteen income groups, eleven types of family composition and seven occupational classifications (such as wage earners, salaried and independent businesses and professions, and retired persons).

This should make it possible to learn who calls on the services of physicians, dentists, ophthalmologists and other specialists, who visits clinics, how much money families in each of these classifications are spending for hospitalization, private nurses and visiting nurses, and what their expenditures are for medicines and drugs, medical appliances and supplies, eye glasses, and health and accident insurance.

These facts will be presented in relation to other family expenditures for food, clothing, shelter, household furnishings and equipment, education, recreation, travel, tobacco, reading, gifts, automobiles and personal care. In addition, changes in family assets and liabilities during the year will be analyzed, so it will be possible to learn the relation between expenditures for medical care and family savings or debts.

Organizations of manufacturers, retailers, advertising agencies and newspapers have shown great interest in the study because of its significance as a comprehensive market research survey. Obviously it will be equally significant for the medical profession in attacking the problems of medical economics and planning for the education of specialists and the location of hospitals. It provides the kind of accurate and objective data needed as the basis for future professional policies.

Such a study as this cannot be truly representative or of maximum usefulness to all groups unless individuals in all groups cooperate. This fact has been recognized by all who have understood the purposes of the study. The economists who planned the study estimated that about 15 per cent of the persons concerned would be unable or unwilling to participate in completion of the short interviews. Instead, the percentage of

¹ Jellison, W. L. and Kohls, G. M. Pub. Health Rep. 51: 842 (June 26) 1936.

'refusals' has averaged 29 per cent. For the longer interview the 'refusals' have averaged 11.5 per cent instead of the 25 per cent estimated.

The selected families of wage earners, retired persons, salaried and independent business men and members of various professions are giving information that will be of great value to the medical profession. The departments involved request the medical profession for similar cooperation. The ultimate usefulness of the study depends of course on the cooperation of the families in each business and professional group and on that of the medical profession.

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

ALABAMA

Deaths from Poliomyelitis—One death reported during the week ended September 25 brings the total number of deaths from infantile paralysis in the Alabama outbreak to twenty-six. For several weeks the total has remained at twenty-five. The total number of cases reported during the period January 1 to September 25 is 354, an increase of eight cases since the preceding report. For the period January 1-September 18 there were 346 cases. For the period ended September 11 335 cases were recorded. The incidence continues to be heaviest in Jefferson, Lauderdale, Morgan, Franklin, Limestone and Cullman counties, with sporadic cases appearing throughout the state.

CALIFORNIA

Health at San Diego—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of thirty-seven million, for the week ended September 19, indicate that the highest mortality rate (166) appears for San Diego and the rate for the group of cities as a whole, 10. The mortality rate for San Diego for the corresponding period last year was 135 and for the group of cities, 10.3. The annual rate for eighty-six cities for the thirty-eight weeks of 1936 is 12.3, as against a rate of 11.5 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

State Association News—The public health institutes sponsored by the California Medical Association will be conducted in Monterey, October 7-11, San Francisco, October 14-17. The first one opened in Santa Barbara, October 2, to continue to the twenty-fourth. The November itinerary will cover the San Joaquin Valley. Visualization exhibits, which were part of the display in the Hall of Medical Science of the San Diego Exposition, will be shown in connection with the institutes. Drs. Edward M. Pallette, Los Angeles, Howard Morrow, San Francisco, and Frederick C. Warnshuis, San Francisco respectively president, president-elect and secretary of the state association, will inaugurate their annual visits to county societies, October 7-10, when five county units will be visited in the upper Sacramento Valley. Not one of the twenty-two state initiatives appearing on the November ballot relate to medicine, medical care, insurance or health legislation.

COLORADO

Personal—Colorado College recently conferred the honorary degree of doctor of science on Dr. Gerald B. Webb, Colorado Springs.

Society News—Dr. Moses Paulson, Baltimore addressed the Denver Society of Internal Medicine, August 17, on "Newer Aspects of Gallbladder Disease, Regional Ileitis and Ulcerative Colitis."—At a meeting of the Medical Society of the City and County of Denver, September 1, Drs. Joseph J. Reilly and Clifford L. Wilmoth, both of Denver, spoke on "Myasthenia Gravis" and "Inguinal Hernia" respectively.—At a meeting of the Northeast Colorado Medical Society in Sterling, September 4, Dr. Vera Hemm Jones, Denver, discussed the state public health program.—Dr. John C. Pounden, Cedaredge, addressed the Delta County Medical Society, August 28, on "Health Insurance in England."

DELAWARE

State Medical Meeting at Rehoboth, October 12-14—The Medical Society of Delaware will hold its annual convention in Rehoboth, October 12-14, with headquarters at the Belhaven Hotel, under the presidency of Dr. Joseph B. Waples Jr., Georgetown. Speakers will include:

Dr. William F. Bonner, Wilmington, Bronchiectasis.
Dr. Ervin L. Stambaugh, Lewes, Acute Appendicitis.
Dr. Arthur C. Jost, Dover, Diphtheria Immunization in Children.
Dr. John W. Burke, Washington, D. C., Facts, Fads and Fancies of Ophthalmology.
Dr. Thomas Grier Miller, Philadelphia, Diagnosis and Management of Gallbladder Disease.
Dr. Bartholomew M. Allen, Wilmington, Results of Gallbladder Examinations by Varying X-Ray Technique.
Dr. Thaddeus L. Montgomery, Philadelphia, Obstetric Anesthesia and Analgesia: Its Effect on the Third Stage of Labor.
Dr. Ira Burns, Wilmington, Recent Advances in Radiotherapy.
Dr. Lawrence J. Rigney, Wilmington, Diagnostic Features of Some Gastro-Intestinal Conditions.

At the meeting of the women's auxiliary, October 14, Miss Effa Wilson of the Delaware Children's Association will be guest speaker.

DISTRICT OF COLUMBIA

Dr. Boone Honored—Dr. Joel T. Boone, commander of the naval hospital, San Diego, Calif., has been awarded the Legion of Honor Medal, the highest award of the French government for extraordinary valor and courage during the World War. Dr. Boone, who was White House physician to Presidents Harding, Coolidge for a part of his term, and Hoover from 1929 to 1933, has been a naval medical officer since 1914. Dr. Boone has been awarded the Congressional Medal of Honor and the Distinguished Service Cross from the United States.

GEORGIA

Society News—At a meeting of the Fulton County Medical Society in Atlanta, September 17, Dr. James G. McDanel, Atlanta, read a paper entitled "A Comparative Study of Syphilis and Nonsyphilis on Fulton County Relief Rolls."—Dr. Kennon C. Walden, Waycross, addressed the Ware County Medical Society in Waycross, August 5, on diseases of the gallbladder.—At a meeting of the Coffee County Medical Society in Douglas, August 25, Dr. Alton M. Johnson, Valdosta, spoke on "Pylorospasm in Infancy."—Speakers before the Fourth District Medical Society at Warm Springs, August 10, included Drs. Arthur Neal Owens, New Orleans, on "Principles of Plastic Surgery as Applied to the Immediate Handling of Accidents", Wilmer Baker, New Orleans, "Handling of Accidents Occurring During the Administration of Anesthesia", Launcelot Minor Blackford, Atlanta, "Cardiac Pain", and Frank K. Boland, Atlanta, "Immediate Care of Fractures."—Dr. Loren Gary Jr., Shellman, addressed the Randolph County Medical Society in Cuthbert, September 3, on the diagnosis and treatment of early syphilis.

ILLINOIS

Society News—The McDonough County Medical Society was addressed at Macomb, September 24, by Drs. William I. Pickett, Chicago, on thyroid surgery, Joseph E. F. Laube, Chicago, hematuria, and Robert S. Berghoff, Chicago, diseases of the heart. Dr. Berghoff also conducted a heart clinic.—Dr. Margarete M. H. Kunde, Chicago, discussed endocrine therapy before the Iroquois County Medical Society at Watseka, September 24.—At a meeting of the DuPage County Medical Society, September 23, Dr. Max Thorek, Chicago, discussed "Photography as a Doctor's Hobby."—The Hancock County Medical Society was addressed, September 14, by Dr. Charles P. Blair, Monmouth, on "Fractures of the Spine" and Harold M. Camp, Monmouth, "The County Medical Society and the Community."

Chicago

Lectures on Psychoanalysis—Among other lectures and seminars, the Institute for Psychoanalysis offers the following during the first quarter of 1936-1937:

Drs. Franz G. Alexander and Thomas M. French, "Psychoanalytic Interpretation of Psychotic Cases."
Dr. Helen Vincent McLean, "Application of Psychoanalysis to Literature."
Drs. Catherine C. L. Bacon and Leon J. Saul, "Case Seminar for Psychiatric Social Workers."

Branch Meetings—At a meeting of the Englewood branch of the Chicago Medical Society, October 6, Dr. Roscoe G. Leland, director, Bureau of Medical Economics, American Medical Association, will speak on medical economics and Dr. Olin West, Secretary of the Association, will open the discussion. Dr. Emil Novak, Baltimore, addressed the Ave Plaines branch, September 25, on "Cause and Treatment of Functional Uterine Prolapse."

IOWA

Neuropsychiatric Meeting—The fifteenth annual convention of the Central Neuropsychiatric Association will be held in Iowa City, October 9-10. Scientific sessions will be held in the medical amphitheater of the University Hospital, with headquarters at the Jefferson Hotel. Speakers, all of Iowa City except Dr. Doolittle, will include:

Dr. William L. Woods: Qualitative Analysis of Deterioration in Schizophrenia and Organic Psychoses
Dr. William Malamud: Psychasthenia
Dr. Erich Lindemann: Pharmacodynamic Studies in Relation to Neurophysiology and Psychopathology
Dr. Stephen Weisz: Studies in Equilibrium Reaction
Lee E. Travis, Ph.D., Berger: Brain Rhythms in Neuropsychiatric Cases
Emil Witschi, Ph.D.: Hypophyseal Tumors Caused by Ovarian Hyperfunction
Dr. Charles G. Barer: Torula Infection of Central Nervous System
Drs. Harold W. Lovell and Harold D. Kerr: Encephalography in Schizophrenia
Prof. Rollin M. Perkins, S.J.D.: Legal Aspects of Neuropsychiatry
Dr. Russell C. Doolittle, Des Moines: The Scope of the Private Sanatorium
Dr. Adolph L. Saba: Dietary Factors in Polyneuritis
Dr. Olan R. Hyndman: Neurosurgical Cases of Special Neurologic Interest

The annual banquet will be held Friday evening with Dr. John F. Fulton, Yale University, New Haven, Conn., as the guest speaker. His subject will be "Autonomic Function Controlled by the Cerebral Cortex."

MAINE

Society News—At a meeting of the Hancock County Medical Society in Bar Harbor, August 25, Drs. Fritz B. Talbot, Boston, and Martin H. Fischer, Cincinnati, discussed "Benefits of Water in Infancy" and "Nephritis," respectively.—Dr. Charles Hendee Smith, New York, addressed the Somerset County Medical Society in Lakewood, August 7, among others, on infant feeding.—The Washington County Medical Society was addressed in Calais August 21, by Prof. Francis G. Benedict, Boston, on "Physiology of the Elephant," and Drs. Russell J. Collins, East St. John, N. B., and George F. Skinner, St. John, N. B., on medical and surgical treatment of tuberculosis, respectively.

Annual Fall Clinical Session—The fourth annual fall clinical session of the Maine Medical Association will be held in Waterville, October 15-16, with headquarters at the Elmwood Hotel. The clinical demonstration and conferences will be held during the mornings and afternoons of both days at the Central Maine Sanatorium, Fairfield, the Elm City Hospital, the Sisters' Hospital and Thayer Hospital. Each day will be divided into four periods, with eight clinics to each period. Thursday evening the Kennebec County Medical Association will hold its regular monthly meeting, the program will consist of a panel discussion on poliomyelitis with Drs. John A. Kolmer, Philadelphia, Josephine B. Neal, New York, and William Lloyd Aycock and Arthur T. Legg, Boston, as the speakers. The program Friday evening will be under the auspices of the committee on medical economics of the Maine Medical Association.

MASSACHUSETTS

Ether Day—Dr. Paul Dudley White, assistant professor of medicine, Harvard Medical School, will deliver the principal address at the observance of Ether Day at Massachusetts General Hospital, October 16. A scientific program will follow a buffet luncheon.

Chair in Legal Medicine Named for Dr. Magrath—"The George Burgess Magrath Endowment for Legal Medicine" will be established at Harvard Medical School, Boston, with a gift of \$250,000 by Mrs. Frances Glessner Lee of Chicago and Littleton, N. H., according to the *New York Times*. The gift commemorates her late brother, John G. M. Glessner, and his classmate at Harvard in 1894, Dr. George Burgess Magrath, medical examiner of Suffolk County since 1907. In that year Dr. Magrath became instructor in legal medicine, a position he held until 1931, when he was named professor. He is 66 years of age.

MINNESOTA

Society News—Dr. John H. J. Upham, Columbus, President-Elect, American Medical Association, discussed medical economics at the Mayo Clinic, Rochester, August 21.—Edgar Allen, Ph.D., professor of anatomy, Yale University School of Medicine, New Haven, addressed a special staff meeting of the Mayo Clinic, Rochester, September 10 on "Hormones in Relation to the Development of Malignant Disease" and Howard B. Anderson, Sc.D. biologist, U. S. Public

Health Service "Carcinogenetic Substances." Others on the program included Drs. Warren H. Lewis, department of embryology, Carnegie Institution of Washington, and Henri Coutard, chief, department of x-ray therapy for cancer, Radium Institute of the University of Paris.

Naturopath Sentenced to Prison for Abortion—George R. Viger, Minneapolis, pleaded guilty in the district court of Ramsey County, September 15, to performing an abortion and was sentenced to a term of not to exceed four years in the state prison, according to the state medical board. Viger was arrested August 7, following the death of a 27-year-old woman at Ancker Hospital, St. Paul. Prior to 1931 Viger maintained an office in the Bremer Arcade in St. Paul, representing himself as a naturopathic physician. He was arrested on a charge of practicing healing without a basic science certificate and pleaded guilty, Dec. 10, 1930. He was sentenced to pay a fine of \$200 and to serve a year in the St. Paul workhouse. The fine was paid and the sentence suspended on condition that he refrain from practicing healing. He closed his office after informing the court that he was moving to Texas. He did not leave the state and at the time of his last arrest was found to be living at a Minneapolis hotel.

MISSISSIPPI

Society News—Speakers before the Northeast Mississippi Thirteen Counties Medical Society at Amory, September 15, included Drs. Robert A. Strong, New Orleans, on "Nutritional Requirements in Infancy", Wade H. Sutherland, Booneville, "Tuberculosis a Surgical Disease", Harvey F. Garrison, Jackson, "Immunization", Richard A. Street, Jr., Vicksburg, "Suprarenal Cortex Hormone," and Stanley A. Hill, Corinth, "Diagnosis of Uterine Hemorrhage."—Dr. Hiram W. Kostmayer, New Orleans, addressed the Central Medical Society, September 1, on "Endocrines in Gynecology."—At a special session of the state legislature recently, an appropriation of \$36,000 was approved to continue the two-year medical school at the University of Mississippi.

Clinics for Crippled Children—The crippled children's service of the state vocational board, cooperating with the state board of health, has arranged a series of clinics to care for children in Mississippi crippled by infantile paralysis since June 1. The first clinic was held, September 16, in Iuka for patients in Tishomingo County; the second at Corinth, September 18, for patients in Alcorn, Tippah and Prentiss counties; the third at Columbus, September 24, at Tupelo, September 26. A clinic is scheduled for Clarksdale, October 3. Scattered cases in central and southern Mississippi will be cared for early in October. These clinics are purely to apply braces, splints and such apparatus to prevent as much deformity as possible and minimize the amount of operating needed later to give the children useful limbs. Since the last legislature did not make the necessary appropriation for matching federal funds for crippled children's service, an appeal was made to Dr. William DeKleene, Washington, D. C., medical director, American National Red Cross, who allotted \$2,625, a similar amount was then obtained from the federal government, and the combined total will be used to finance the program.

MISSOURI

Public Health Program at Clinical Conference—A public health meeting, Monday evening, will be a feature of the Kansas City Southwest Fall Clinical Conference, October 4-8. Speakers will be Drs. Jay Arthur Myers, Minneapolis, Milton A. Bridges, New York, and Morris Fishbein, Chicago, editor of *THE JOURNAL*. Their subjects will be respectively "Driving Tuberculosis from Our Midst," "Facts and Fallacies Regarding Food and Diet," and "Your Heart and Your Life." A new item about the conference appeared in *THE JOURNAL*, September 12, page 883.

NEW YORK

District Meetings—The annual meeting of the Sixth District Branch of the Medical Society of the State of New York was held in Ithaca, September 17. Drs. Chevalier Jackson and Chevalier L. Jackson, Philadelphia, presented a paper on "Diseases of the Lungs" and Dr. John C. M. Brust, Syracuse, "Diagnosis and Treatment of Anal Abscess and Fistula." Drs. Stafford L. Warren and Charles M. Carpenter, Rochester, displayed colored motion pictures on heat treatment of gonorrheal infections, Dr. William A. Brumfield, Jr., Albany, of the state health department, discussed the state syphilis control program and Dr. John K. Deegan, Albany, described the new

Hermann M Biggs Memorial Hospital, Ithaca Addresses on state society affairs were made by Drs Floyd S Winslow, Rochester, president, David J Kalisk, New York, chairman of the workmen's compensation bureau, and Peter Irving New York, secretary — These officers of the state society and Dr Frederic E Elliott, Brooklyn, chairman of the committee on economics, also addressed the annual meeting of the Seventh District Branch at Willard September 24 Drs Arthur Krida, New York, and William J Merle Scott, Rochester, spoke on "Surgery of the Knee Joint" and "Differentiation of Benign and Malignant Lesions in the Gastro-Intestinal Tract." Dr Ross E Herold, clinical director of the Willard State Hospital, conducted a dry clinic and Dr Edward G Winkler, Buffalo, presented a motion picture showing various procedures in gynecology

New York City

First Harvey Lecture—Dr Wilder G Penfield, professor of neurology and neurologic surgery, McGill University Faculty of Medicine, Montreal, will deliver the first Harvey Lecture of the season at the New York Academy of Medicine, October 15 His subject will be "The Relation of the Cerebral Cortex to Consciousness"

The Academy's Ninth Graduate Fortnight.—The New York Academy of Medicine will present its ninth annual graduate fortnight during the two weeks October 19-31 on "Trauma, Occupational Diseases and Hazards" Clinics will be held in various hospitals from Monday to Friday each week in the afternoons, and scientific addresses will be delivered each evening at the academy building Dr Henry E Sigerist, professor of the history of medicine, Johns Hopkins University School of Medicine, Baltimore, will deliver the Wesley M Carpenter Lecture Monday evening October 19, on "The Historical Background of Industrial and Occupational Disease." On a special program arranged by the Medical Society of the County of New York for Monday evening October 26, Hon. Bernard L Shientag and Hon. Meier Steinbrink, justices of the state supreme court, will discuss "The Workmen's Compensation Law Its History and the Lessons It Holds for the Future" and "The Medical Witness" respectively Among other speakers will be

- Dr Alfred Blalock Nashville Tenn, Shock and Hemorrhage
- Dr Marvin A Stevens New Haven Conn Hazards in Athletics
- Dr Alice Hamilton Boston Medicolegal Aspects of Industrial Poisonings
- Dr Temple S Fay, Philadelphia Results of Treatment of Cerebral Trauma Based upon the Laws of Cerebral Hydrodynamics
- Dr John J Moorhead Accidents and Their Management
- Dr Robert H Kennedy The Medical Problem in First Aid
- Dr Foster Kennedy Fatigue and Noise in Industry
- Dr James Ewing Relation of Trauma to Malignant Tumors
- Dr William Darrach General Principles of Fracture Treatment
- Dr James M Hitzrot Hand Injuries
- Dr Frederic W Bancroft, Burns Thermal and Electrical Radiant and Chemical
- Alexander O Gettler Ph D, Toxicology of Industrial Poisonings
- Dr Byron P Stookey Nonoperative versus Operative Treatment of Spinal Cord Injuries Associated with Vertebral Fractures and Dislocations
- Dr Arthur M Wright Trauma of the Abdomen
- Dr Francis B Berry Trauma of the Chest.
- Dr George F Cahill Trauma Involving the Kidney the Ureter and the Bladder

Thursday evening, October 22, speakers will be Major Samuel A White, medical corps, U S Army, on "Medical Aspects of Chemical Warfare", Col Adeline Gibson, U S Army, "Chemical Warfare as Developed During the World War—Probable Future Development," and Dr Henry H M Lyle, "Treatment of Injuries Caused by High Explosives" The following evening the program will be on the relation of trauma to diabetes, discussed by Dr Elliott P Joslin, Boston, pulmonary disease, Dr James Burns Amberson Jr, cardiovascular disease Dr Bernard S Oppenheimer, and the nervous system, Dr Israel Strauss

PENNSYLVANIA

Unlicensed Practitioner Fined—Mike White of Washington County was convicted September 8 of practicing medicine without a license. A \$250 fine and costs or ninety days in jail was imposed The case was handled through the division of law enforcement of the state department of public instruction, of which the state board of medical education and licensure is a part.

Philadelphia

Society News—The first fall meeting of the Philadelphia County Medical Society was held September 23 Dr Francis Ashley Faught was installed as president succeeding Dr George C Yeager—The Philadelphia Laryngological Society cele-

brated its twenty-fifth anniversary September 15—Dr Walter Schiller, assistant at the Frauenklinik, University of Vienna, addressed the Obstetrical Society of Philadelphia, September 24 on "Early Diagnosis of Carcinoma of the Cervix"

Dr Anders' Will—Dr James M Anders, who died August 29 provided in his will that after the death of his widow \$50,000 of his estate is to go to the University of Pennsylvania to establish the James M Anders Foundation in the Graduate School of Medicine. Dr Anders also bequeathed \$2,500 to the Philadelphia County Medical Society to defray the expenses of the annual "Public Health Day" in the public schools, \$2,000 for the endowment fund of the society's library, and such books from his library as the library committee may select.

RHODE ISLAND

Division of Industrial Hygiene—The state department of health has established a division of industrial hygiene through funds available under the social security act Dr James Philip Deery, Wallum Lake, is director of the division and Dr William A. Mahoney, Providence, assistant director Dr Deery was graduated from Georgetown University School of Medicine, Washington, D C, in 1932 and Dr Mahoney from Tufts College Medical School, Boston, in 1919

Society News—The Providence Medical Club made its second annual pilgrimage August 19 to the home of Dr William Hunter, who in 1755-1756 delivered at Newport the first systematic series of medical lectures in this country The club was entertained by Miss Anna Falconet Hunter, great great granddaughter of Dr Hunter, and visited the site of his apothecary, the house in which he lived, the Newport Historical Society, where many memorials of him are preserved and the churchyard where he was buried in 1777, at the age of 47

UTAH

Plague Infection—Under date of August 24, plague infection was reported in fleas taken from twenty-three prairie dogs, *Cynomys parvidens*, shot on a ranch two miles east of Hatch, Garfield County Plague infection was reported, under date of August 26, to have been proved by mass inoculation of material from two prairie dogs shot August 6 on a ranch five miles northeast of Panguitch, Garfield County, according to *Public Health Reports*

VIRGINIA

State Medical Meeting at Staunton.—The sixty seventh annual session of the Medical Society of Virginia will be held at Staunton, October 13-15 with headquarters at the Hotel Stonewall Jackson Dr William D Haggard, Nashville Tenn, will give an address at the opening general session, Dr Lloyd W Ketron, Baltimore, will address a general session Wednesday on "Tuberculosis of the Skin," at which Dr Philip St L Moncure, Norfolk, will give his presidential address, on "The South in Medicine and Surgery" Virginia speakers on the program will include

- Dr Harvey B Haag, Richmond Studies on the Persistence of Action of Digitalis and Digitalis Bodies
- Dr Walter B Martin Norfolk Adhesive Pericarditis with Decomensation Treatment by Evulsion of the Left Phrenic Nerve
- Dr Emmette T Gatewood Richmond Bronchoscopic Observation of Laryngotracheobronchitis in Children with Obstructive Dyspnea
- Dr Charles W Putney Staunton Treatment of Fractures of Long Bones by Use of an Improved Fracture Reducing Frame
- Drs John H Neff and Edgar W Kirby Jr University Prostatic Obstruction
- Dr William Lowndes Peple, Richmond, Radium in Treatment of Non-malignant Diseases of the Uterus
- Dr Linwood D Keyser, Roanoke Stone in the Urinary Tract

There will be a symposium on endocrine diseases presented by Drs Edward L Alexander Newport News, Charles J Andrews, Norfolk, and Edwin P Lehman University

WASHINGTON

Society News—Dr James W Henderson Longview was elected president of the Public Health League of Washington at the annual meeting September 1 in Yakima—Dr Howard B Kellogg addressed the King County Medical Society Seattle October 5 on "Regional Ileitis" and Drs Donald V True blood Clyde R Jensen and Terence T Dawson gave a five year report of the tumor clinic at the King County Hospital

WISCONSIN

State Medical Election—Dr James C Sargent Milwaukee, was chosen president elect of the State Medical Society of Wisconsin at the annual meeting in Madison September 10 and Dr Stephen E. Gavin Fond du Lac was installed as president. The 1937 meeting will be in Milwaukee

GENERAL

Poliomyelitis Closes Schools—Opening of schools in Ashtabula, Ohio, was deferred because six cases of poliomyelitis were reported in the city September 8.—Schools in West Pottsgrove, Pa., were closed September 10, for several days after a case of infantile paralysis was found in a family with several children of school age.

Decline in Appendicitis Death Rate—A steady decline in the mortality rate from appendicitis among industrial policyholders of the Metropolitan Life Insurance Company has been noted in the five year period 1931-1935, according to the *Statistical Bulletin*. In the age group 1 to 74, the rate dropped steadily from 143 per hundred thousand in 1931 to 11.5 in 1935, a decrease of 20 per cent. Among white male policyholders the rate last year, 135 per hundred thousand, was the lowest recorded in this group since 1919, while the rate among white women policyholders was the lowest registered in twenty-five years. Provisional figures for the first seven months of 1936 indicate that the death rate from appendicitis will drop to an even lower level this year than in 1935. In the period 1931-1935 the death rate was the highest (211) for white male policyholders in the age group 65-74, the same age group showing the highest rate (19) among white women policyholders.

Cancer Death Rate for 1935 Highest on Record—In a recent analysis of deaths from cancer, Frederick L. Hoffman, LL.D. Biochemical Research Foundation of the Franklin Institute, Philadelphia, points out that the cancer death rate for 184 cities with a population in 1935 of nearly 46,000,000 was 125.6 per hundred thousand of population against a rate of 123.1 in 1934, establishing the highest death rate from this cause since records have been carefully observed. The actual number of deaths in the 184 cities increased from 55,201 in 1934 to 57,309 in 1935, while 107 cities reported increases and seventy-seven decreases in their cancer death rates. The ten cities with the highest cancer death rates were Madison, Wis., 286.8, Concord, N. H., 238.4, Portland, Me., 229.4, Pasadena, Calif., 218, Troy, N. Y., 187.6, Boston, 187.3, Shreveport, La., 185.2, Pittsfield, Mass., 183.5, Spokane, Wash., 182.8, and Quincy, Ill., 178. In the five largest American cities, Chicago, Detroit, Los Angeles, New York and Philadelphia, the highest rate (147.5) was returned for Philadelphia. Detroit was the only city in this group to show a decrease (67.8). Presenting comparative rates in certain foreign countries, Dr. Hoffman points out that Switzerland reported an increase from 115.8 per hundred thousand of population in 1907 to 147.3 in 1934. Death rates, based on specified types, were 43.2 per thousand for cancer of the female genital organs in single women (25 years old and over), compared with 64.6 for married, widowed and divorced women. For cancer of the breast the rate for single women was 54.6, and for married, widowed and divorced women it was 49.1.

The International Society of Surgery—The International Society of Surgery, founded in 1905 at Brussels through the initiative of the Belgian Surgical Society under the leadership of Drs. Charles Willems of Ghent and A. Depage of the University of Brussels and surgeon in chief of the Belgian army, will hold its next session in Vienna in September 1938. The society now has nearly 2,000 members, who represent forty-five nations. Fellowship is obtained solely by recognized professional merit based on the recommendation and endorsement of a national committee on credentials in each of the constituent countries. A triennial congress is held. The scientific program continues for three days and is devoted mainly to the discussion of live and controversial questions of immediate importance to the profession. These subjects are selected long in advance by an international committee, to be debated by essayists or rapporteurs selected from the five countries whose languages are officially recognized by the congress. The essays are translated into five languages (French, English, German, Italian, Slav [Polish] and Spanish) and distributed to the fellows long in advance of the congress. The affairs of the society are managed by a council consisting of representatives elected by the delegates of each one of the constituent countries with the aid of an executive committee or bureau permanently established in Brussels, consisting of an executive chairman (Professor Verhoogen), the secretary general (Dr. Mayer), the treasurer (Dr. P. Lorthioir), and the president and vice presidents as ex officio members. Dr. Leopold Mayer of Brussels has been the general secretary during the thirty-one years of its existence. The World War suspended the activities of the society from 1914 to 1920 when the fifth congress was held in Paris under the presidency of Prof. W. W. Keen of Philadelphia. Thus far the congresses have been held in Brussels, New York, Paris, London, Rome, War-

saw, Madrid and Cairo. Its presidents have been Kocher of Bern, Czerny of Heidelberg, Lucas-Championnière of Paris, Depage of Brussels, Keen of Philadelphia, Macewen of Glasgow, Giordano of Venice, Hartman of Paris, de Quervain of Berne, von Eiselsberg of Vienna and Rudolph Matas of New Orleans. Dr. Lorthioir of Brussels, who had been the treasurer of the society since its foundation, was elected at Warsaw but died before he could preside at Madrid in 1932 and was succeeded by de Quervain, vice president, who officiated in his place. Professor von Eiselsberg, who was to have presided at Cairo, was ill in Vienna, and Dr. Schoenmaker of The Hague, vice president, presided in his place. The American constituency of the society is one of the largest in the organization. Out of a maximum quota of 150 members allowed for the United States, 127 American surgeons—all distinguished by their rank and the merit of their contributions, have been admitted to fellowship on the recommendation and endorsement of the American committee, which at present consists of Dr. Elliott C. Cutler, professor of surgery at Harvard (chairman), and Drs. Eugene H. Poole of New York, and Rudolph Matas of New Orleans. The eleventh congress will be held at Vienna in September 1938 under the presidency of Dr. Rudolph Matas, emeritus professor of surgery, New Orleans, with Profs. Ferdinand Sauerbruch of Berlin and S. Hybbinette of Stockholm, vice presidents. The subjects selected for special discussion are (1) the surgical treatment of arterial hypertension, (2) bone grafts and (3) the surgical treatment of cysts and tumors of the lungs. The conducted sight-seeing tours usually provided by the society for the convenience and entertainment of those who attend the congress are being planned for the congress through Czechoslovakia, Hungary, Dalmatia and other countries of special interest to tourists.

Society News—The International Association of Police and Fire Surgeons and Medical Directors of Police and Fire Surgeons and Medical Directors of Civil Service Commissions will hold its annual meeting at the Hotel Taft, New Haven, Conn., October 8-10.—The annual meeting of the Southwestern Medical Association will be held in El Paso, Texas, November 19-21. Guest speakers will be Drs. Harold Brunn, San Francisco, Thomas E. Carmody, Denver, Ralph A. Kinsella, St. Louis, James T. Case, Chicago, Warren T. Vaughan, Richmond, Va., Nels F. Ockerblad, Kansas City, Mo., Willard R. Cooke, Galveston, Texas, and Isidore Cohn, New Orleans.—The next annual session of the American Therapeutic Society will be held in Atlantic City, June 4-5, 1937. Dr. Chevalier L. Jackson, Philadelphia, is president and Dr. Oscar B. Hunter, Washington, D. C., secretary.—The American College of Physicians has purchased a residence at Forty-Second and Pine streets, Philadelphia, to establish permanent headquarters.—The American Association of Industrial Physicians and Surgeons will meet in Atlantic City, October 7-9, at the Traymore Hotel.—The American Dietetic Association will hold its nineteenth annual meeting at the Hotel Statler, Boston, October 12-15. Speakers will include Drs. Chester M. Jones on "Protein Deficiencies", Walter Bauer, "Diet for Arthritis", George R. Minot, "Anemias of Nutritional Deficiencies", Charles Macfie Campbell, "Diet of Psyche", Wilson G. Smilie, "Place of the Nutritionist in Public Health Programs". All are of Boston. Vilhjalmur Stefansson, Ph.D., New York, will address the annual banquet on "Adventures in Diet".

FOREIGN

Malaria Congress Postponed—The third International Congress on Malaria, scheduled to be held in Madrid October 12-18, has been postponed on account of the present situation in Spain, it is announced. It is hoped to convene the congress sometime during the spring or summer of 1937. Dr. E. Luengo, Madrid, is general secretary.

Society News—The first European Congress of Reconstructive Surgery was to be held in Brussels, October 3-4.—The ninth International Congress of Military Medicine and Pharmacy will be held in Bucharest, Rumania, May 8-14, 1937. Subjects to be considered include organization and functioning of health service in the combined operations of armies of land and sea, transport, hospitalization and treatment of gassed persons, surgical service for motorized troops.—The Holland Gynecologic Society at Amsterdam is to organize an International Congress for Obstetrics and Gynecology in connection with its fiftieth anniversary in 1938. It is reported. The secretary of the committee organizing the congress is Dr. F. C. van Tongeren, University Clinic for Obstetrics and Gynecology, Wilhelmina-Gasthuis, Amsterdam. W.

Sept 12, 1936

Lord Moynihan Is Dead

The death of Lord Moynihan in his seventy-first year has removed the foremost figure in British surgery. While suffering from the blow of his wife's death, which he felt severely, he had a seizure, never recovered consciousness and survived her only a week. The son of an Irish officer who served with distinction in the Crimean war and Indian mutiny, he was trained at the Leeds Medical School and graduated M.B. in the University of London in 1887. In 1893 he passed the examination for master of surgery and received the gold medal. He was appointed a teacher of anatomy at the Leeds Medical School and later assistant surgeon. His progress was rapid. In 1909 he became professor of surgery in the Leeds Medical School, in 1912 he was knighted and was elected to the council of the Royal College of Surgeons and in 1926 to the presidency, a position which he held for the unprecedented period of six years. In 1918 he was made a baronet and in 1928 he became Baron Moynihan of Leeds. In the great war he was consulting surgeon to the British expeditionary force. Academic honors were showered on him from all over the world.

Moynihan began his career as a general surgeon, but he soon devoted himself to the surgery of the stomach, gallbladder and intestine, of which he became the leading exponent in this country. The subject was in its infancy when he began to work at it in association with another great abdominal surgeon, the late Mayo-Robson. Together they wrote a book on Diseases of the Stomach, which was published in 1901, at a time when little was known of the subject from the surgical standpoint. Moynihan was not long in impressing his remarkable personality on the surgery of the abdomen and in raising the previously high reputation of the Leeds school to its zenith. Enthusiastic energetic in testing the latest ideas of others and in producing his own a beautiful operator and a master of trenchant exposition his clinic and his writings attracted the whole surgical world. He was indeed, as Rutherford Morison termed him, 'a live wire'. He was the British counterpart of J. B. Murphy for whom he had an intense admiration, as the first Murphy memorial lecture delivered by him to the American College of Surgeons at Montreal in 1920 shows. He was incomparably the best speaker in the profession and one of the very few in its history who could be called an orator. He could without hesitation deliver a perfectly phrased lecture without a note, though it is said that he previously memorized his lectures. His most important work was first delivered as addresses to medical societies, which were later collected and published in book form. His command of language enabled him to crystallize his teaching in telling phrases which live.

PATHOLOGY OF THE LIVING

In an address with the title "The Pathology of the Living" he contrasted the pathology of the living with the pathology of the dead. He pointed out that the knowledge gained during an operation showed that the postmortem evidence was of small value compared with that which had been furnished during the life of the patient. It was of greater import to see the actual condition in life of an organ that was abnormal than to see it months or years afterward when unalterable and extensive advances and perhaps terminal infection had been added to the simpler original cause or the disturbance in health. It was of much more importance to know the pathologic conditions that caused present suffering—a chance that perhaps

was remediable—than to know the fullest particulars of an unhindered morbid change that at last caused death. This was a favorite thesis, to which he returned again and again.

INAUGURAL SYMPTOMS

Closely connected with the preceding subject was another address given under the title of "Inaugural Symptoms" in 1908. He pointed out that when the textbooks of medicine were written it was the late symptoms and signs which were thought to be characteristic. But late symptoms were too often the heralds of death, while inaugural symptoms might be the cry for timely surgery. There was need for the earnest investigation of inaugural symptoms. Malignant disease came too often to surgeons when the time for safe operative treatment was past. "We hesitate to diagnose cancer of the stomach before a lump can be felt. We question the evidence of duodenal ulcer until hemorrhage occurs, although it is a late, dangerous and preventable complication. We dare not hint the presence of gallstones till jaundice comes, though symptoms of the plainest meaning have been present for years. Indeed, much of the textbook symptomatology urgently demands revision."

GASTRIC AND DUODENAL ULCER

Perhaps his most important work was done in connection with the diagnosis and treatment of gastric and duodenal ulcer. He described the symptoms with great acumen and introduced the term "hunger pain" to describe a pain caused by the taking of food and appearing a few hours after the meal, which occurred both in gastric and in duodenal ulcer and was always associated with hyperchlorhydria. In gastric ulcer the pain gradually disappeared before the next meal, but in duodenal ulcer it continued until the next meal or until food was taken to relieve it. Thus the rhythm of gastric ulcer was quadruple: food, comfort, pain, comfort; of duodenal ulcer, triple: food, comfort, pain. Duodenal ulcer, which was far more common than gastric ulcer, could always be diagnosed with considerable confidence by the history.

THE DIAGNOSIS OF GALLSTONES

He pointed out that the error carried down from one generation to another—that in the majority of cases gallstones cause no symptoms—had been dispelled by the work of the surgeon. In operating in an advanced case of cholecystitis a history of inveterate, though perhaps trivial, dyspepsia could almost always be obtained. The symptoms were fulness, weight distention or oppression in the epigastrium coming on soon after meals, usually within half or three quarters of an hour, relieved by belching and dismissed almost on the instant by vomiting, elicited with remarkable constancy by certain articles of diet.

THE EARLY DIAGNOSIS AND TREATMENT OF CANCER

He was never tired of impressing both the public and the profession with the importance of the early diagnosis of cancer. Too many physicians were skeptical about the good results that could be obtained from surgical treatment and in too many cases allowed the patient to drift into the condition that made recurrence after operation inevitable. Wait and see was wrong; the advice should be 'Go and look at once.' His incentive power of speech is shown by the way he startled a large audience in the house of the British Medical Association assembled to hear a popular lecture on the cancer problem. If the law of averages holds 100 persons in this room will die of cancer."

HIS WORK FOR THE SURGICAL PROFESSION

An ardent reformer, a man of consummate tact, impressive both to the profession and to the public, an excellent administrator, he was able to bring about more and greater changes in the

surgical profession than were ever before accomplished by one man. He filled the office of president of the Royal College of Surgeons with great distinction. Before his time the college was regarded by many as an examining body with an admirable museum, in connection with which valuable lectures were delivered. Under his lead extensive provision was made for experimental research, both at the college and at the Buxton Browne Research Farm, which was established at Downe in Kent. He was very keen on research, but he objected that physiology, in spite of its stupendous growth, had little interest in man and was becoming more and more remote from him. The immediate requirement was a better knowledge of the normal man and of the "near normal man." A new science of "paraphysiology" was required. He took the lead in the foundation of the *British Journal of Surgery* and during the whole period was chairman of the editorial committee. He saw that the surgeons of this country kept too far apart and he founded the Moynihan Surgical Club the members of which spend a week together visiting hospitals abroad and meet for a second time in the year to visit a hospital in which one of them works. He was also prominent in founding the Association of Surgeons of Great Britain and Ireland. His last enterprise was the presidency of the Voluntary Euthanasia Legalisation Society, which was formed at the end of 1935 to make legal relief by death of painful incurable disease. He was to introduce a bill on the subject in the house of lords.

The Sterilization of Catgut

The recent occurrence of several groups of cases of tetanus, following operations in which catgut was used, has caused the Ministry of Health to issue a memorandum on this danger. The therapeutic substances regulations allow the sale of sterilized ligatures and sutures only under a license, the granting of which is conditional on the routine testing for sterility of samples from each batch of catgut manufactured or imported while the premises, staff and methods of manufacture are controlled by periodical inspection. But in some hospitals catgut is still used which is not so controlled. It is bought raw and is "sterilized" in the hospital by a process which may or may not be satisfactory. In nine cases (of which five proved fatal) which recently came under the notice of the ministry, the evidence pointed to such "home cured" catgut as the source of infection.

In a report rendered to the Scottish board of health in 1928 Mackie analyzed the evidence in eleven cases of postoperative tetanus that occurred between 1920 and 1928 in a single hospital which was supplied with catgut from one source and concluded that the evidence pointed definitely to catgut as the source of infection. The danger of insufficiently sterilized catgut is therefore evident.

The sterilization of catgut is an elaborate and difficult process. As many as fifty-one methods have been used and many of them have been found not to be reliable. Destruction of the spores of the tetanus bacillus is the great difficulty. Mackie found that, if the unspun ribbons were soaked in hydrogen peroxide for twelve hours and the spun strings treated with iodine water for eight days, the excess of iodine being then removed by washing in alcohol, a sterile gut with good physical properties was produced. The conclusions of the Ministry of Health are as follows: 1. Serious dangers attend the use of raw catgut or so-called internally sterilized catgut to which sterilizing processes of doubtful efficiency are applied in the hospital. 2. Many brands of efficiently sterilized catgut controlled under the therapeutic substances act are available. 3. Postoperative tetanus, gas gangrene and other infections from surgical catgut can be prevented by the use of catgut manufactured by licensees under the act.

PARIS

(From Our Regular Correspondent)

Aug. 22 1936

Organized Medicine and the Forced Retirement Bill

In a recent letter, reference was made to a bill termed the Pomaret bill, which proposes to relieve the congested condition in the liberal professions. If the bill is passed, which at present seems unlikely, all lawyers, architects, physicians and druggists will be obliged to surrender their diplomas at the age of 65 and be forced to retire from active practice without any remuneration in the form of a government pension.

The interests of the medical and dental professions in France in such matters is looked after by "syndicats," or associations which unfortunately do not include as members as large a proportion of the physicians and dentists as do the corresponding associations in the United States. Nevertheless the influence of these "syndicats" is considerable here, and they are making a strong fight against passage of the Pomaret bill, and the chances at present are that the proposed forcible retirement clause of the law will never reach a stage beyond that of discussion. The *Confédération des syndicats médicaux français* which includes all the local protective associations, in its August bulletin states that the idea of permitting every physician to retire at the age of 65, if he so desired, has been provided for by this association in collecting money for a mutual insurance fund, so that an annuity could be paid, enabling a physician at the age of 65 to add such a sum to any funds already set aside by him and thus permit him to live comfortably. But this retirement should remain an entirely voluntary affair. When the government delivered a license to practice in the past, no time limit as to its use was set, and hence the contract cannot be broken by one of the parties alone. The confederation is of the opinion that a voluntary retirement is not to be objected to but that retirement should not be compulsory unless an adequate annuity is given by the state to every physician who is obliged to cease practice at 65, and that half of the annuity should be given to the physician's widow in case of decease.

At the July 19 meeting of the executive committee of the *Confédération des syndicats médicaux français*, the following resolutions were passed as an expression of the opinion of the confederation on "bill 151 (Pomaret)" tending to assure immediate and steady employment of French youth:

1. No such law, affecting unrestricted practice of medicine, should have been deposited as a bill before the legislature without consulting organized medicine.

2. The federation will oppose with all the resources at its disposal the limitation of the license to practice beyond the age of 65 years. A voluntary retirement cannot be objected to, provided a fund is established by the government so that an adequate annual pension can be given those who wish to retire at the age of 65. Such a fund is to represent the total of annual obligatory premiums paid by all practicing physicians collected by the government and set aside as a mutual insurance fund for the voluntary retirement of physicians.

3. The naturalization of foreign-born physicians and medical students must be immediately prohibited. The illegal practice of medicine and quackery, as well as the unethical exploitation of pharmaceutical preparations, should be more strictly controlled than at present.

This third resolution aims to correct an abuse of the laws passed in 1935 which did not permit foreigners to be granted licenses to practice. In spite of this apparently strict regulation, many foreign born applicants for state licenses have overcome the objections by becoming naturalized and thus the overcrowding of the profession has been but little relieved.

The uncontrolled exploitation of all forms of quackery and drugs here justly merits the demand of the federation for stricter supervision

Treatment of Acute (Staphylococcic) Osteomyelitis

The treatment of acute (staphylococcic) osteomyelitis is still being discussed at the Académie de chirurgie, the leading surgical society of Paris. In the letter published in *THE JOURNAL*, June 13, papers read by Leveuf and Mathieu were referred to in which a plea was made, based on a relatively extensive experience, not to operate in cases of acute osteomyelitis due to staphylococci until the acute local and general symptoms had subsided.

At the May 27 meeting the discussion was continued by Sorrel, who has charge of a large children's surgical service in Paris and thus has ample opportunity to see such cases. He stated that the portal of entry is most frequently some skin lesion which fails to attract attention at the time when the involvement of the bone medulla manifests itself. Although the bacteria are carried by way of the blood vessels, blood cultures are negative until the acute bone symptoms appear at the same time as the general evidences of a septicemia, at which period the blood cultures become positive. An article by Bariety on staphylococcic septicemias published in the *Semaine des hôpitaux* in February was cited by Sorrel, showing that the body possesses defense mechanisms which act on the bacteria circulating in the blood, by lysis, fixation or elimination. In order that a septicemia should persist, a constant supply, i. e., multiplication of bacteria, must take place. In an acute osteomyelitis, it is the bone focus which furnishes such a constant supply. There are cases of acute osteomyelitis in which the symptoms of a general septicemia dominate the clinical picture. Such patients are more often observed by internists than by surgeons. Between these two, predominantly local and predominantly generalized cases, many intermediate cases are seen by both internists and surgeons, and it is in these that the question arises as to what form of treatment should be adopted.

Another point of interest is one conceded by bacteriologists, viz., that the staphylococcus is a poor antigen and hence that vaccination against this type of infection is difficult or impossible. This explains the slow healing of osteomyelitic foci and the frequency of exacerbations after apparent recovery.

These two facts permit one to say, first, that well localized osteomyelitic foci can be the starting point of septicemia and of secondary foci and, secondly, that the spontaneous defense mechanism of the body is powerless because it can produce but few and often no antibodies. As Mathieu stated at a previous meeting the forms under which an acute osteomyelitis can present itself clinically vary so greatly that the same treatment for all cases is impossible. As to general treatment, much was expected of vaccinations but the results have not been very encouraging. The same has been true of the bacteriophage and immunotransfusion treatment. The future alone will reveal whether the use of the Ramon staphylococcus anatoxin will be of any value.

The surgical treatment ought not to be the same for all cases. One should be guided by the local lesions and the evolution of the infection in general.

Sorrel believes that the only cases of acute osteomyelitis in which a late operation should be performed are those in which a staphylococcic septicemia exists but the bone involvement is for a long time of secondary importance. These patients should be operated on only when the general symptoms have subsided. Such cases are relatively rare. Sixty-two cases of acute osteomyelitis have been treated by Sorrel since 1931 and fifty-nine of these were due to staphylococci. Eleven of the fifty-nine patients died and recovery was more or less complete in forty-

eight. In twenty-eight cases the general infection was a severe one with extensive bone involvement. Twenty-six of these patients were operated on by resection and two by trephining, with two deaths in patients having multiple foci. In six cases the bone lesion was of secondary importance as compared to the general infection. Five of these six patients died.

Until the staphylococcus anatoxin and antistaphylococcus serum proves to give good results, Sorrel believes that early operations, such as simple incision of a subperiosteal abscess, trephining or diaphyseal resection, are indicated. Only in the severe septicemic form is a delayed operation justifiable.

The discussion was continued by Boppe, who stated that if a trephining operation is not followed by subsidence of local and general evidences of infection, a resection of the entire shaft should be performed. Boppe was in favor of delayed operation. A large number of patients, operated on late or not at all, had recovered following immobilization supplemented by general treatment. There are cases, however, in which one has the impression that the expectant method has been harmful. The prognosis of a given case of acute osteomyelitis presents many unknown elements. With the exception of blood cultures, an element of definite gravity but not at all of fatal prognostic significance, there are no sure tests which permit one to judge the evolution of an osteomyelitis.

Convention of German Phthisiologists

At the recent annual convention of phthisiologists the question of legal measures in furtherance of the antituberculosis campaign was discussed. The groundwork for a greater centralization of antituberculosis activities was laid when the centers for the care of the tuberculous throughout Germany were placed under the supervision of officers of the public health service and the latter organization thus assumed the care of tuberculous patients as a part of its legitimate duties (*THE JOURNAL*, Sept. 22, 1934, p. 932, June 1, 1935, p. 2011). Four papers on the question of legal regulation were submitted to the congress and are herewith summarized. The protection of children and young people against infection with tuberculosis by persons not belonging to the family is of the utmost importance. It was demanded that in social institutions, based on legal compulsion, such as the schools, yearly physical examinations of both teacher and pupil be made obligatory. Any person found to be infected should be segregated from his fellows. A recent decision of the reichsgericht (the highest German tribunal) expressly fixes responsibility of the appointed officials. Before admission to certain semivoluntary groups (youth organizations, apprenticeships and so on) the candidate must be certified as free from tuberculosis. In voluntary relationships such as domestic service and the kindergarten, employers and parents should demand certificates of health for employees or children from the antituberculosis centers. Further legislation to supplement that already in force should provide for amplification of the present law on compulsory reporting of tuberculosis cases, compulsory medical examination at the tuberculosis stations, prophylactic measures (compulsory isolation if necessary), sanitary supervision of certain occupational groups, and more drastic measures of disinfection. In order to protect the community against occupational tuberculosis the exercise of certain callings should be forbidden a person who presents an active infectious tuberculosis, the person so excluded to be indemnified of course, against economic distress. Furthermore compulsory examination of both healthy and sick persons should be stipulated such examination to include roentgenography of the thorax. Since the entire popu-

lation cannot be examined simultaneously, local sanitary officials should be empowered to select the persons to be examined at a given time. Compulsory treatment is both necessary and practicable. It might consist of detention in an institution or of surgical intervention, thoracoplasty, for example. If the patient withholds consent to an operative intervention that promises to be successful, compulsory curative measures should be carried out until the patient is no longer able to spread the infection to others, the costs of such treatment to be divided between the patient himself and the public health service. Repeated reference was made to the successful experimentation with compulsory isolation of asocial tuberculous patients which has already been attempted in Thuringia (*THE JOURNAL*, Oct 19, 1935, p 1284). The discussion that followed the reading of these papers showed that the phthisiologists as a whole approved of the new measures suggested. Both the papers and the discussion are of especial importance, since they provide a substantial foundation for new antituberculosis legislation.

Klare of Scheidegg submitted a report on active pulmonary tuberculosis in children and young persons. The follow-up control of 502 actively tuberculous children and youths who received treatment at Klare's institution during the years 1916-1933 yielded a gloomy prognostic picture. (Control was effected by means of triennial follow-up questionnaires.) The chances for recovery of patients under the age of 7 who present far advanced forms of the disease are poor, for this group a mortality of 95.5 per cent was determined at the end of ten years. For patients under the age of 13, the corresponding death rate is lower by 15 per cent, but 80 per cent is still a shockingly high figure. Klare hopes to be able to reduce the mortality to 75 per cent or perhaps even to 65 per cent, lower values can scarcely be obtained, as puberal influences seem to impair all the organism's forces of defense against phthisis. Lymphatism is always to be regarded as a favorable indication in tuberculous children and adolescents. Early detection of the disease may favor recovery by making possible the institution of an active therapy (collapse treatment). Cavernous decomposed early infiltrates above all can almost without exception be brought to a healing by means of a timely initiation of collapse therapy.

Böhne of Hamburg stated (on the basis of 20,000 cases examined) that the Meimicke tuberculosis reaction is markedly specific. By it active pulmonary tuberculosis as well as widespread bone and genital tuberculosis can be determined. The test fails however, to establish quite recent infiltration. The activity and extent of the process run principally parallel to the intensity of the reaction manifested. Inactive cases exhibit negative reactions. The Meimicke reaction is above all of practical value for the detection of pathologic processes that are not clinically and roentgenologically demonstrable.

With regard to measures of disinfection, E. Gabe stated that the danger of infection from dust irritation has been grossly exaggerated. Guinea-pigs, for example, will remain healthy even after a twenty-four hour stay in the dusty atmosphere of a room in which blankets and clothing of tuberculous persons have been beaten out. Dust specimens from the floor of the solariums for the tuberculous, from other rooms and from washing water after the cleaning of the wall paper were all found to be free from tubercle bacilli. In institutional hygiene, the discipline is the most important factor and chemical disinfectants are to a great extent considered unnecessary. For blankets formaldehyde disinfection and for linen boiling are the methods of choice. The complete destruction of the excreta is of the utmost importance since danger of infection through the drainage is thus obviated.

Finally the question of the significance of thoracoplasty was discussed. Graf of Coswig stated that investigations carried on during the past fifteen years have consistently led one to

form the opinion that disintegrating tuberculous cavities in the lungs, or at least those which develop to medium size and endure for a number of months, excepting in rare instances, do not come again to a healing without operative intervention. Such cavities are a constant menace to the patient's life and, besides, their presence means a serious risk of acquiring the infection for persons in proximity to the sufferer. Thoracoplasty should be resorted to in proper cases if pneumothorax and its supplementary measures prove insufficient. Thousands of patients who otherwise would have been lost have thus operation to thank for their recovery. During the past ten years various types of this intervention have been worked out that not only bring about an authentic healing of the cavernous areas, which are situated for the most part in the upper portion of the lungs, but also make it possible to preserve the still healthy pulmonary tissue on the affected side.

Aug 14, 1936

The Ninth International Dental Congress

The largest of all dental organizations, the *Fédération dentaire internationale*, is accustomed to hold a quinquennial scientific convention. The ninth congress of the federation was held early in August at Vienna. For the last two and one-half years a local committee of sixteen, of which Professor Dr. Pichler was chairman, had been preparing for this gathering. In working out a program it was decided that each forenoon was to be devoted to the reading of papers on the more recent investigations of the last five years and the afternoons were to be given over to demonstrations, carried out before small groups, of various special therapeutic methods and examination procedures. To reduce to a minimum the linguistic difficulties of an international convention, for the first time at one of these congresses a method was used that has been proved serviceable in the deliberations of the League of Nations. The speaker had a microphone before him and his speech was listened to by interpreters, wearing earphones, who were housed in closed booths. As the words of the speaker were received by the interpreters the latter would immediately translate orally into a microphone, and an amplifying system would then convey the translated speech to the audience seated in the hall. The speeches were broadcast in German, French and English and the listening delegate could select whichever language he wished by means of an apparatus attached to his chair. Thanks to a corps of first class interpreters, the translations were made so rapidly that a listener could well believe that the speaker was talking in any of the three tongues. In addition, each delegate was presented prior to the transactions with a two volume 1,600 page edition of all the original discussions to be read. This meant that only the remarks of the open discussions would be new to the audience. Altogether some 4,000 dentists from forty-five different countries participated in the proceedings. Prof. G. Villain of Paris occupied the chair. After the addresses of welcome by the governmental and academic dignitaries the presentation of the international Miller prize for the most important work of the last five years took place. Profs. Maurice Roze of Paris, Bernhard Gottlieb of Vienna and A. Cieszyński of Lwow each received the gold medal.

Proceedings were held simultaneously in three large assembly halls and reflected throughout the tremendous interest of the participants. In section 1 Professor Grumbach of Zurich as principal speaker, read a paper on focal infection. Our increased knowledge of oral sepsis has brought with it new and perplexing problems and it has brought to light the relation of the teeth to various diseases. In many disease condi-

tions formerly loosely ascribed to cryptogenic sepsis," focal infections are now inculcated. Under "focal infection" are classified those disease conditions characterized by the presence of a chronic hidden focus of infection from which at greater or lesser intervals bacteria and their toxins enter the blood and give rise to various pathologic manifestations. About the teeth such foci are particularly apt to take the form of the so called apical granulomas, from which bacteria in many instances are carried to the blood. Such granulomas may thus be the cause of rheumatism, nephritis, defects of the cardiac valves, septic processes, febrile conditions and a whole catalogue of other diseases. This theory, which originated in America, is not as vigorously defended as it was ten years ago.

Professor Palazzi of Milan discussed the trend in the last five years toward more detailed histologic and anatomic dental examinations. Professor Shour of Chicago spoke on the interrelation of the endocrine glands and the teeth, he stressed the fact that these glands exert an important influence on the normal formation of the teeth. Bisection or cauterization of the sympathetic nerves in the region of the gonads (Doppler's operation) has an incontestably favorable effect on various diseases of the gums (pyorrhea alveolaris). In addition, the relation of the parathyroid glands to calcium oxide metabolism, first discovered by the Viennese anatomist Erdheim, is of especial importance.

In section 2, discussions of the substitution of artificial teeth were furnished by Dr Stansbery of Seattle and Professors Fish of London, Villain of Paris and Wustrow of Greifswald. The last named exhibited models to prove that in mastication with a plate prosthesis a force of some 15 Kg can be placed in action without any damage to the mucous membrane lying beneath the prosthesis. In section 3 the history of dentistry was the principal topic. A paper by Professor Salamon of Budapest on the dental bridge was of interest. Dental bridges were introduced into Europe from America by Thomas Evans in 1860. Evans also made known the first set of india rubber teeth in Europe. Substitution of artificial teeth was known to remote antiquity, in ancient Egypt, Etruria and Phoenicia there were dentists capable of fashioning excellent dental bridges. The art subsequently became lost and was revived in the first third of the eighteenth century. The historical development of the treatment of the roots and the use of anesthesia in dentistry is likewise extremely interesting. In the year 1870 the dental engine, then driven by foot power, was first introduced, several years later came the engine driven by electricity.

The causes and treatment of dental caries was the principal topic on the second day. Professor Bunting of America reported on the investigations undertaken by the so-called Michigan Research Group, which is composed of dentists, bacteriologists and biochemists. It has been ascertained from these investigations that the causative agent of dental caries is an organism of the *Bacillus acidophilus* type. This organism is always present in carious dental substance and can be detected in the saliva of patients with dental caries. It is not to be found, on the contrary, in persons immune to the disease. The Michigan investigators undertook nutritional tests in the form of group examinations of the different dietetic regimens in use among school children and institutions. Indications were that the ingestion of foods containing calcium oxide phosphorus vitamin D or alkaline nutriment is virtually without influence on dental caries.

On the other hand the old finding was confirmed that a regimen rich in sugar fosters the propagation of *Bacillus acidophilus* and therewith caries. Conversely, studies of the saliva showed that the development of this bacillus is impaired in a diet deficient in sugar. The type of nutriment was regarded by this group of investigators not as in relation to the chemistry of the bodily fluids but as exerting a direct

influence within the oral cavity proper, in the immediate surroundings of the teeth. The possibility of producing a protective substance against caries had been demonstrated and inoculation experiments had already been attempted. If *Bacillus acidophilus* was present in the oral cavity, inoculation might even produce dermal reactions. The protective substance against caries seemed to be present in the blood, so one should consider the possibility of a systematic inoculation therapy in caries.

A paper by Professor Euler of Breslau on dental defects conditioned by the nutriment dovetailed admirably with that of the Michigan men. In teeth, discovered in excavation that probably are about 4,000 years old, Euler was able to establish dental caries in only 1.5 per cent of the skeletal remains, a contrast to the frightfully high present-day incidence. The speaker called attention to the decalcifying action of lactic acid and described how the carious process is furthered by the lodging of food remnants (especially particles of sweet foods) between the teeth. Honey forms an exception, it causes no fermentation in the mouth and since it contains formic acid and formaldehyde (although in small amounts, to be sure) it acts as a mild antiseptic. Professors Weayre of London and Paffenberger of Washington and Drs. Bauer of Innsbruck, Joachim of Brussels and Smreker of Vienna provided discussions of the various problems presented by caries and other dental material. Dr. Weinmann was able to prove the existence in the saliva of a protective substance against caries. The salivary corpuscles contain a ferment-facilitating decomposition of protein that is found in smaller quantities in carious subjects and in larger quantities in the noncarious. Weinmann was able further to show that persons inclined to have carious teeth secrete much less saliva than persons with healthier mouths. The bactericidal power of the saliva is also connected with the salivary corpuscles. The latter, somewhat like the leukocytes, form a sort of police force.

One section of the congress concerned itself with discussions of dental education. Thorough descriptions of the organization of instruction in dentistry in their respective countries were provided by speakers from Poland, Japan, France, Hungary and Austria. In Austria the title "zahnarzt" (dental physician) is protected by the most rigid legal restrictions. In that country every dentist must first be a regular doctor of medicine and then spend four additional semesters in dental studies after which he must pass a rigorous examination in the field. The Austrian system of regulation has come to serve as a model for the other countries of Europe. Interesting too was a paper by Dr. Mansbach of Palestine on the dental hygiene examination of a large number of children between the ages of 3 and 12. Children from rural communities where the diet is chiefly vegetarian presented an almost complete immunity from caries, whereas among children from Jerusalem and other urban areas there was a substantial incidence of dental caries.

The problem of anesthesia took one entire morning session of the congress. Two opposing schools engaged in debate the adherents of narcosis and the adherents of injection anesthesia. Professor Sicher of Vienna states as a fact that, in every country where the study of maxillary anatomy has attained a high level, injection anesthesia rather than the more mechanical procedure of narcotic anesthesia is the method of preference.

Professor Parma of Prague, speaking on the problem of roentgenology, declared that no enterprising dentist could reckon without it. Some roentgenograms of teeth were exhibited. Interest attached to the problems of treating and filling the roots. In recent years the formerly overdone practice of extracting diseased teeth has fortunately been sharply checked and dentists generally have come to favor the killing and filling of the diseased roots. The pulp, the living dental marrow, is indeed the most precious part of any tooth and should be pre-

served as long as possible. In England, in Switzerland and in Austria, special prominence is accorded this problem. Gottlieb of Vienna in particular has devised a unique method: he does not subject the living pulp to treatment with medications but removes it under anesthesia by a purely surgical procedure. By this means the connective tissue is stimulated to a new formation of adamantine. There has as yet, however, been no agreement as to the method to be employed in the treatment of gangrenous pulp.

One section concerned itself exclusively with the question of dental hygiene in the school. In Vienna as early as 1911 this problem was partially solved but not till 1922 was a systematic effort made to cope with it. Drs. Driak and Greiner, both of Vienna, submitted discussions. Austria at present boasts forty school dental clinics, eighteen of which are located in Vienna. Whereas in the year 1922 less than 4,000 children were at any one time under the supervision of the school dental hygiene service, in the year 1934-1935 91 per cent of Austrian school children (namely 127,000) were under observation of these school clinics. Of the latter number more than 60 per cent were recorded as in need of treatment and 86 per cent of these were subsequently discharged with healthy sets of teeth.

Similar reports came in from other countries. In Oslo, Norway, for example, of 25,000 children examined, only 160 were free from dental caries. Dr. Witthaus of the Netherlands traced defective maxillary development to the use of stupidly devised sucking bags and to the habit of thumb and finger sucking in infancy. Premature loss of the temporary teeth inhibits proper mastication, and this gives rise to impaired maxillary development. Witthaus believes that caries of the permanent teeth is dependent on and conditioned by caries in the temporary teeth. He discountenances the unrestricted nibbling of sweets and advocates the eating of raw fruits at the conclusion of a meal as a means of cleansing the teeth.

Dr. Kantorowicz, who now resides in Istanbul, was the organizer of a systematic program of dental hygiene in the schools of Germany, his former home. By ordinary hygienic procedures he was able to maintain healthy dentition in 90 per cent of the German school children. Kantorowicz also postulated the extension of dental hygiene to the temporary teeth, the instruction of children in careful dental hygiene, early correction of defective dentition, and prophylaxis for diseases of the dental bed. These fundamentals should be carried on with the child of school age and later extended to the entire population, effecting as it were a systematic national dental hygiene. Kantorowicz cited Palestine as the example of a country where the campaign against a neglect of oral hygiene has gone forward with success.

The discussions of pyorrhea alveolaris marked the culmination of the congress. This disease leads to an atrophy of the gums and not infrequently to an involvement of otherwise healthy teeth, which in turn brings about an irremediable loosening process. Pyorrhea claims no fewer victims than caries. The interest of the entire medical world in this formidable problem of public health is therefore readily understandable. Prof. Maurice Roye of Paris (winner of the Miller prize) attacked the question of pyorrhea with a substantial discussion of the influence of defective heredity. He suggested that defective arrangement of the teeth and disturbances of the bite facilitate the loosening process. Professor Entin of Leningrad discussed the pathologic anatomy of the condition: atrophy of the gums and the formation of pus pockets may be taken as characteristic. The last named manifestation is not yet well understood: it is believed that disturbances of the metabolism and of the glands of internal secretion are etiologic factors in the disease. Of persons suffering from pyorrhea alveolaris 67 per cent are between 30 and 40 years of age; there is a

higher incidence among women of this age group. Dr. Entin is of the opinion that the gastro-intestinal system figures in the etiology of the disease. He believes that observation of the nervous system will yield important indications. Disorders of the intestine, kidneys and liver also all too frequently coincide with dental disturbances.

Professor Häupel of Prague discussed his own philosophy of the etiologic factors in pyorrhea alveolaris. It is his belief that any general illness which is influenced by cellular metabolism is capable of producing pyorrhea. The disease has an extremely high morbidity in many countries. According to Häupel, it is more frequent among slender types than among the stout. It may appear as a sequel to infectious disease, notably influenza. Dr. Weinmann of Vienna interposed that he had observed a hypofunction of the anterior lobe of the hypophysis in pyorrhea alveolaris patients. Professor Häupel for his part had often observed that Doppler's operation leads with virtual experimental certainty to an amelioration of the purulent and loosening processes. Doubtless too, important roles are played by local factors such as tartar or the irritation set up by ill fitting artificial teeth. Häupel recommends as therapeutic measures the application of oxygen and of escharotics, and the opening and eradication of the pus pockets. The goal is the restoration of healthy gums and to accomplish this an adequate dental hygiene is also necessary.

Dr. Orman of the Viennese school is of the opinion that two forms of pyorrhea alveolaris may be differentiated, the one due solely to neglect of oral hygiene, the other dependent on disturbances of the general metabolism. To be sure, the medical procedure is identical for the two forms. The first consideration is always a painstaking removal of the tartar and the pus pockets. Any course of treatment will be rendered useless if the patient is not made conversant with the correct technique of the tooth brush, a knowledge that should be inculcated in childhood. Any defects of dentition should be corrected as quickly as possible. At best the treatment of pyorrhea alveolaris will require an unusual amount of time and patience.

A round of social functions together with the usual excursions and receptions brought to a close the proceedings of the ninth congress.

Marriages

NORMAN R. SLOAN to Mrs. Catherine Flynn Ward, both of Christiansted, St. Croix, Virgin Islands, August 27.

WILLIAM FREDERICK I. DEY, Saratoga Springs, N. Y., to Miss Margaret Rawlings of Poughkeepsie, June 12.

JOSEPH F. BENJAMIN, Ridgewood, N. J., to Miss Agnes Sweeney of Glen Rock, August 1.

ERNEST HENRI KEUTMANN to Miss Harriet Kenyon Todd, both of Rochester, N. Y., June 18.

JAMES BORDLEY III, Baltimore, to Miss Julia Peabody Ross of Chestnut Hill, Pa., July 4.

MARTIN F. ZIEGLER, Chicago, to Miss Louise Anne Simon of Elkhart, Ind., September 20.

SAMUEL MACON CARRINGTON to Miss Nellie Upchurch, both of Oxford, N. C., July 17.

VERNON A. WEED to Miss Marjorie Kuidert, both of Red Lake Falls, Minn., June 21.

GEORGE L. KRESS, Warsaw, Ind., to Miss Aline Welsheimer of Columbia City, June 14.

ROBERT A. BROWN JR. to Miss Virginia Harris, both of Greenville, S. C., May 22.

WALTER S. BOOTH, Elizabeth, N. J., to Miss Matilda Mary Nogi of Linden, June 27.

KINLOCH NELSON to Miss Alice MacGill Deford, both of Richmond, Va., July 23.

ARNOLD I. WEBMAN, Fremont, Neb., to Miss Lucille Polishuk of Chicago, June 21.

Deaths

Frankwood Earl Williams ♂ New York, medical director of the National Committee for Mental Hygiene from 1922 to 1931, died, September 24, of acute intestinal obstruction while aboard the White Star liner *Georgic*, aged 53. Dr. Williams was born in Cardington, Ohio, May 18, 1883. He attended high school in Indianapolis and received the bachelor of arts degree from the University of Wisconsin in 1907 and the medical degree from the University of Michigan Department of Medicine and Surgery, Ann Arbor, in 1912. He was first assistant physician at the Boston Psychopathic Hospital from 1913 to 1915, medical director of the Massachusetts Society for Mental Hygiene from 1915 to 1917, chairman of the Massachusetts Advisory Prison Board from 1916 to 1917, associate medical director of the National Committee for Mental Hygiene from 1917 to 1922, and then medical director until 1931. During the World War he served as first assistant and chief of the division of neurology and psychiatry in the office of the Surgeon General of the army and was a lieutenant colonel in the Officers Reserve Corps from 1919 to 1929. He was a member of the American Psychoanalytic Association, the American Psychiatric Association, the New England Society of Psychiatry, the American Psychopathological Association and the American Orthopsychiatric Association. Dr. Williams was chairman of the mental hygiene section of the National Conference on Social Work from 1917 to 1919 and from 1922 to 1924 vice chairman of the National Health Council from 1922 to 1923, member of the administrative board of the Institute of Child Guidance of the Commonwealth Fund from 1927 to 1931, member of the advisory council of the New York Health and Tuberculosis Demonstrations and also the Milbank Memorial Fund until 1931, and member of the board of directors of the New York Psychoanalytic Institute. He was also a member of the teaching staff of the Smith College for Social Work, Northampton, Mass., from 1921 to 1926 and the New York School of Social Work in 1924. From 1926 to 1929 he was a lecturer on psychiatry at the Yale University School of Medicine and from 1930 to 1932 at the Columbia University College of Physicians and Surgeons. In 1927 he received the honorary degree of doctor of science from Colgate University, Hamilton, N. Y. He contributed many books and periodical articles on mental hygiene to the literature of recent years and was the editor of *Mental Hygiene* from 1917 to 1932.

John Leo Burkart ♂ Big Rapids, Mich., Victoria University Medical Department, Coburg, Ont., Canada, 1874, Faculty of Medicine of Trinity College, Toronto, Ont., Canada, 1877, also a pharmacist, at one time state health commissioner, past president and secretary of the Mecosta County Medical Society, for many years professor of pharmacology and therapeutics at the Grand Rapids Medical College, postmaster, and for many years health officer, veteran of the Spanish-American War, aged 83, member of the staff of the Mercy Hospital, member of the staff and secretary of the Community Hospital, where he died, July 12, of coronary sclerosis.

George Frank Holland ♂ Bloomington, Ind., University and Bellevue Hospital Medical College, New York, 1903, past president of the Monroe County Medical Society, fellow of the American College of Surgeons, veteran of the Spanish-American and World wars, district surgeon to the Illinois Central Railroad and local surgeon to the Monon Railroad, surgeon to the Bloomington Hospital, aged 64, died July 15, in the Methodist Episcopal Hospital, Indianapolis, of carcinoma of the prostate.

Lucien P. McCalla, Bellingham, Wash., Missouri Medical College, St. Louis, 1888, member of the Washington State Medical Association, past president of the Whatcom County Medical Society, formerly a practitioner in Boise, Idaho, for many years a member of the state board of medical examiners of Idaho, at various times on the staffs of St. Luke's General Hospital and St. Joseph's Hospital, aged 70, died suddenly, July 17, at Georgetown, Texas.

Dennis Ralph McElhinney ♂ Elizabeth, N. J., University of Pennsylvania Department of Medicine, Philadelphia, 1903, past president of the Union County Medical Society, fellow of the American College of Surgeons, president of the medical staff and attending surgeon on the visiting staff of the Alexian Brothers Hospital, secretary of the staff and attending surgeon on the visiting staff of St. Elizabeth Hospital, aged 56, hanged himself, July 30.

Martin Isaac Marshak ♂ Bayonne, N. J., University and Bellevue Hospital Medical College, New York, 1911, served

during the World War, formerly city physician, on the staff of the Bayonne Hospital, attending physician to the Hudson County Parental Home, at one time superintendent of the Sanatorium of the Jewish Consumptives' Relief Society, Spivak, Colo., aged 50, died, July 15, of heart disease and renal colic.

Frank McDonald Denslow ♂ Kansas City, Mo., University of Kansas School of Medicine, Kansas City, 1906, member of the American Urological Association, fellow of the American College of Surgeons, served during the World War, consultant in urology, Kansas City General and St. Margaret's hospitals, aged 59, died, July 25, in St. Luke's Hospital of carcinoma of the stomach with metastasis to the liver.

George Alfred Holliday ♂ Pittsburgh, Western Pennsylvania Medical College, Pittsburgh, 1897, formerly treasurer of the Allegheny County Medical Society, member of the American Urological Association on the staffs of the Pittsburgh City Home and Hospitals, Mayview, and St. John's Hospital, aged 64, died, July 9, of carcinoma of the liver.

Horace Palmer Beck, Newport, R. I., University of Pennsylvania Department of Medicine, Philadelphia, 1897, member of the Rhode Island Medical Society and the New England Otological and Laryngological Society, formerly member of the city council, on the staff of the Newport Hospital, aged 62, died, July 5, of heart disease.

James Albert Miller, Grampian, Pa., Western Pennsylvania Medical College, Pittsburgh, 1897, member of the Medical Society of the State of Pennsylvania, past president of the Clearfield County Medical Society, for many years a member of the local school board, aged 75, died July 11, of lobar pneumonia and pyelocystitis.

William Belvidere Meares Jr., Lexington, N. C., University of Virginia Department of Medicine, Charlottesville, 1915, member of the Medical Society of the State of North Carolina, aged 47, died, July 13, in the Johnston-Willis Hospital, Richmond, Va., of pneumonia, following an operation for a tumor of the stomach.

Philip Abernethy Graves ♂ Oak Park, Ill., Dearborn Medical College, Chicago, 1904, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, for many years a member of the staff of the Chicago Eye, Ear, Nose and Throat Hospital, aged 63, died July 17.

William Jones Muzzy ♂ El Reno, Okla., Missouri Medical College, St. Louis, 1897, past president and secretary of the Canadian County Medical Society, fellow of the American Society of Clinical Pathologists, on the staff of the El Reno Sanitarium, aged 69, died, July 12, of carcinoma of the liver.

James Wheeler Miller, Hillsboro, Texas, Vanderbilt University School of Medicine, Nashville, Tenn., 1886, Bellevue Hospital Medical College, New York, 1891, member of the State Medical Association of Texas, past president of the Hill County Medical Society, aged 76, died, July 12.

Frank Manson Brown, Centerville, N. B., Canada, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1885, L.R.C.P., London, L.R.C.P., Edinburgh, L.R.F.P.S., Glasgow, 1887, aged 72, died, June 21, at the L. P. Fisher Memorial Hospital, Woodstock.

Samuel Fisler Ashcraft ♂ Mullica Hill, N. J., Jefferson Medical College of Philadelphia, 1888, past president of the Gloucester County Medical Society, aged 70, died, July 4, in the Jefferson Hospital, Philadelphia, of arteriosclerotic heart disease and prostatic hypertrophy.

Frank John Fara ♂ Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1905, member of the staff of the Hospital of St. Anthony de Padua, aged 55, died suddenly, July 22, in Berwyn, Ill., of coronary thrombosis.

George Cohn, Piggott, Ark., National Medical University, Chicago, 1909, College of Medicine and Surgery, Chicago, 1910, member of the Arkansas Medical Society, aged 59, died July 28, in a hospital at Paragould of injuries received in an ambulance accident.

Oscar Stuart McMullen ♂ Victoria, Texas, University of Tennessee Medical Department, Nashville, 1904, past president of the Victoria-Calhoun County Medical Society, served during the World War, on the staff of the Victoria Hospital, aged 54, died July 6.

Francis James Buss ♂ Chicago, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1901, member of the staffs of the Robert Burns, Belmont and Ravenswood hospitals, aged 60, died July 11, of embolism.

Marguerite Agnes Muller, Charleston S C, Medical College of the State of South Carolina, Charleston, 1931, member of the South Carolina Medical Association aged 31, died, July 5, in the Myers Clinic Hospital, Philippi, W Va, of pneumonia

Ulysses Schuyler Colfax Busch, Cadillac, Mich, University of Michigan Department of Medicine and Surgery Ann Arbor, 1903, at one time member of the school board of Jennings, aged 61, died suddenly, July 13, of cerebral hemorrhage

Ellsworth Paro Mills, Detroit, Detroit College of Medicine, 1899, served during the World War, aged 60, on the staff of the Highland Park (Mich) General Hospital, where he died, July 8, of intestinal obstruction due to adhesions

Eugene Justin McCarthy, Malden, Mass, Tufts College Medical School, Boston 1905 member of the Massachusetts Medical Society, member of the Veterans Administration, Boston, aged 52, died, July 28, in a hospital at Chelsea

Walter Wingart Mannhardt @ Custar Ohio Toledo (Ohio) Medical College, 1903, served during the World War member of the staff of the East Side Hospital Toledo aged 54, was killed, July 18, in an automobile accident

Edward A Scott, Galena, Md University of Maryland School of Medicine, Baltimore, 1886, for many years chief judge of the Orphans Court of Kent County, aged 77, died, June 2, of carcinoma of the prostate and bladder

George G Corbet, St John, N B, Canada, McGill University Faculty of Medicine, Montreal, Que. 1898, fellow of the American College of Surgeons orthopedic surgeon to St John County Hospital, aged 66, died June 8

Ignazio Cangialosi, Hoboken, N J, Regia Università di Bologna degli studi Facoltà di Medicina e Chirurgia, Italy, 1908, Eclectic Medical College of the City of New York, 1910, aged 53, died, July 7, of coronary thrombosis

Thomas James Dougherty @ Somersworth N H, Baltimore Medical College, 1894, formerly mayor of Somersworth, city and county physician, and secretary of the board of education, aged 67, died, July 4, of angina pectoris

Joseph D McKelvey, East Moline Ill, Rush Medical College, Chicago, 1895, member of the Illinois State Medical Society, aged 65, on the staff of the East Moline State Hospital, where he died, July 29, of heart disease

Raymond E Chase @ Glendale, Calif, University of Southern California College of Medicine, Los Angeles 1901, on the courtesy staff of the Glendale Sanitarium and Hospital, aged 57, died, July 13, of coronary thrombosis

Davis Breco, Ada Okla, University of Oklahoma School of Medicine, Oklahoma City, 1933 member of the Oklahoma State Medical Association, on the staff of Breco's Memorial Hospital aged 36 was drowned, July 2

Pablo Gonzalez Jr, Glendale Calif, George Washington University School of Medicine, Washington D C, 1932, aged 28, resident physician on the staff of the Physicians and Surgeons Hospital, where he died, July 23

George Nelson Brazeau, Milwaukee, Northwestern University Medical School, Chicago, 1894 fellow of the American College of Surgeons aged 64, died, July 13, in St Joseph's Hospital, of carcinoma of the rectum

Charles T Bronaugh, New Ross, Ind, Medical College of Indiana, Indianapolis, 1884, member of the Indiana State Medical Association, formerly county coroner aged 82, died, July 23, of carcinoma of the throat

John M Prince, Miami, Fla, National Normal University College of Medicine, Lebanon, Ohio 1890 formerly a practitioner in Philadelphia aged 77, died, June 21, of arteriosclerosis and cerebral hemorrhage

George Mogridge, Glenwood, Iowa, Omaha Medical College, 1894, formerly medical superintendent of the Iowa Institution for Feeble Minded Children, aged 80, died suddenly, July 22, of pulmonary hemorrhage

James Ward McKee, Los Angeles, Tulane University of Louisiana School of Medicine, New Orleans 1916, served during the World War, physician for the public schools in Glendale, aged 47, died July 16

William T Blanton, McCool, Miss University of Tennessee Medical Department, Nashville, 1891, aged 69, died, July 14, in a hospital at Memphis, of leukemia, hypertrophy of the prostate and uremia

Archie Elmer Perkins, Fitchburg, Mass, Hahnemann Medical College and Hospital, Chicago 1889 member of the Massachusetts Medical Society, aged 71 died, June 14 in Gardner of pneumonia

Robert Yandel Shepherd, Taylorsville, Ky, Louisville Medical College, 1907, member of the Kentucky State Medical Association, aged 57, died, June 30, of encephalitis and acute dilatation of the heart

Joseph Omer Pichette, Montreal, Que., Canada, School of Medicine and Surgery of Montreal Faculty of Medicine of the University of Laval at Montreal 1893, aged 65, was found dead in his office, June 26

Samuel Cecil Slocum @ Portland, Ore., Cooper Medical College, San Francisco 1900, for many years member of the city health department, and county coroner aged 60 died July 5, of heart disease

Leslie Ballard Evans @ Windsor, N C University College of Medicine Richmond, 1900 formerly state senator aged 67, died, July 31, in the Tayloe Hospital, Washington, of cerebral hemorrhage

Giuseppe Romano, Cleveland, Regia Università di Palermo degli studi Facoltà di Medicina e Chirurgia Italy, 1904, on the staff of St John's Hospital, aged 58, was found shot and killed, June 10

John Allen Underwood, Wilmar Ark Memphis (Tenn) Hospital Medical College, 1908, aged 61, died, June 14 in a hospital at Little Rock, of cerebral embolism and chronic nephritis

John Henry Finnerty, Jersey City, N J, Bellevue Hospital Medical College, New York, 1884, formerly member of the city board of health, aged 80, died, July 11, of cardiac decompensation

Moses Duckman, Brooklyn, College of Physicians and Surgeons, Medical Department of Columbia College, New York, 1894 aged 67, died, July 23, of coronary thrombosis and arteriosclerosis

John Benjamin Dudley, Bath, N Y, University of Michigan Department of Medicine and Surgery, Ann Arbor, 1877, aged 84, died, July 21, of chronic myocarditis and arteriosclerosis

Max Landower Rothschild @ San Francisco (licensed in California in 1897), medical director of the California Sanatorium, Belmont aged 65, died suddenly, July 12, of heart disease

Stephen J Suwalski, Baltimore, Baltimore University School of Medicine, 1896, also a dentist, aged 77, died, June 24, in Catonville, of chronic myocarditis and arteriosclerosis

John Francis Burns, New York, Georgetown University School of Medicine, Washington, D C, 1925, aged 36 died, July 31, in Thompsonville, Conn, of coronary thrombosis

Christopher J Colles, New York, Universität Heidelberg Medizinische Fakultät, Heidelberg, Germany, 1882, aged 77, died, July 9, in the Midtown Hospital of tuberculosis

Walter Allen Borland, Seattle, University of Oregon Medical School, Portland 1911, aged 62, died June 28, in the Columbus Hospital, of cardiovascular renal disease

Charles William Strobell, San Diego Calif, University of Vermont College of Medicine, Burlington, 1882, aged 78, died, June 25, of coronary thrombosis

Edwin Warren Bullock @ Somerville, Mass, Harvard University Medical School, Boston, 1886, aged 73, died, July 7, of a self inflicted bullet wound

William Blair, Ann Arbor, Mich., University of Michigan Department of Medicine and Surgery, Ann Arbor, 1893, aged 66, died, July 11, of carcinoma

John William Comfort, Kosciusko, Miss, Memphis (Tenn) Hospital Medical College, 1895, aged 67, died, July 12, of coronary thrombosis

Walter Augustus Reilly @ Naugatuck, Conn., Bellevue Hospital Medical College, New York, 1898, aged 60, died, June 3, of angina pectoris

Barton L Tupper, Glidden, Wis, Illinois Medical College, Chicago 1902, aged 66, died, June 22, of arteriosclerosis and myocarditis

John Pleasant Savage, Los Angeles, Miami Medical College, Cincinnati, 1878, aged 80, died, June 12, of coronary arteriosclerosis

Frederick Arthur Edwards, Omaha, Trinity Medical College, Toronto, Ont., Canada, 1901, aged 62, died, July 6, of appendicitis

Jesse E Scott, Kansas City, Mo, Eclectic Medical University, Kansas City, 1907, aged 61, died, June 3, of coronary thrombosis

Bureau of Investigation

THE THERMALAID QUACKERY

The Federal Trade Commission Orders the Electro Thermal Company to Cease False Claims

Toward the end of July, this year, the Federal Trade Commission issued a 'Cease and Desist Order' in the matter of the Electro Thermal Company, a quackish outfit that has for some years done business from Steubenville, Ohio. One W. J. Kirk is described as the president of the Electro Thermal Company. An earlier name for the Thermalaid was 'Electrothermal Dilator'.

The Thermalaid was essentially a rectal dilator consisting of a hard rubber unit to be inserted in the rectum for the application of heat. The heating element was produced by an electric current, and two forms of the device were sold, one to be activated by the electric-lighting current and the other by means of a battery where a lighting circuit was not available.

The Thermalaid has been advertised and sold under the claim, either expressed or implied, that it would cure prostatic hypertrophy and diseases of the prostate. It has also been recommended as a cure for constipation and hemorrhoids (piles) and by implication, as a sexual rejuvenator.

Wm. J. Kirk, the president of the Electro Thermal Company, is not a physician. Victims were obtained by the methods common to mail-order quacks: that of advertising in such newspapers and magazines as are willing to split the profits of quackery with takers of this type. Advertisements of the Thermalaid in the files of the Bureau of Investigation collected during the past few years have come from such publications as:

Physical Culture
Los Angeles Times
Kluwanis Magazine
Popular Mechanics
Detroit Mirror
Police Gazette

True Story
Real Detective
Popular Stories
Correct Eating
Strength
Modern Living

The advertising has also carried the usual number of testimonials. One that was featured extensively was that of Dr. C. Herbert Johnston of Chicago. Dr. Johnston, according to the records of the American Medical Association, was born in 1851 and received an Illinois license in 1885 on the basis of a diploma dated the same year that he claimed to have received from the Physio-Medical Institute of Cincinnati. The diploma could not be verified, for the Cincinnati institution went out of existence the same year that it issued the diploma. While the advertisements would lead one to believe that Dr. Johnston was a prominent physician and especially qualified in the urologic field, the fact is that he is practically unknown to scientific medicine. Records in the files of the American Medical Association indicate that Johnston was once 'vice-president' of a low-grade so-called medical school that operated in Chicago. He also appears to have been a disciple of the late Dr. Albert Abrams, the dean of American quackery.

The names of two other physicians are given as having testified to the alleged virtues of the Thermalaid. One of them who was born in 1861 and died in 1934, received his medical diploma in 1883. In addition to giving a testimonial for the Thermalaid, he also endorsed the 'Magic Dot' rupture-cure quackery put out from Steubenville and debarred from the mails in the spring of 1935.

The other physician was born in 1868 and received his medical diploma in 1891. Whether the man is still alive, the records of the American Medical Association fail to show, as it has been impossible to trace his address since 1922. The files of the Association do indicate, however, that at one time the man was connected with a quackish outfit of the "men's museum" type in an eastern city and at another time had some connection with the Electro-Medical Scientists operated by the notorious Ward in New York City. Still later it was reported that he had entirely given up the practice of medicine either reputable or disreputable and had gone into the theatrical business.

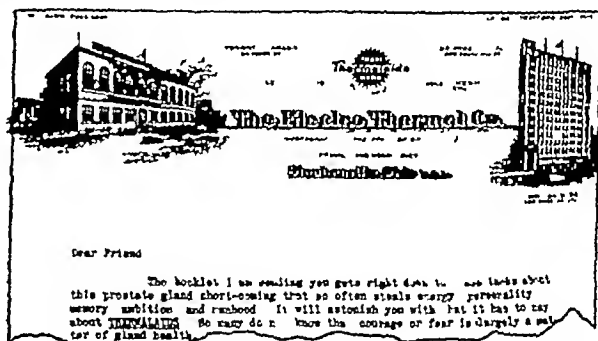

As has been so often detailed in this department of THE JOURNAL, some highly respectable banking institution was used by the Electro Thermal Company to bolster this piece of

quackery. According to the Thermalaid advertising the following individuals, as officers of certain banks, were pleased to "testify" to their "own good opinion of the integrity, responsibility and business ability of the Electro Thermal Company." That the company was financially responsible and had business ability might readily be admitted, but does the exploiting of a quack device under false and misleading claims constitute these gentlemen's idea of "integrity?" The persons and institutions named at the end of this testimonial are:

H. M. Cattell, Treasurer of the Union Savings Bank & Trust Company
A. G. Lee, President of the Steubenville Bank & Trust Company
L. L. Crimes, Cashier of the Peoples National Bank
George J. Barthold, Secretary of the Miners and Mechanics Savings & Trust Company
W. H. McClinton, President of the National Exchange Bank & Trust Company

There was also published among the testimonials one from a Mr. Rawley W. Holcombe who was alleged to have been the manager of the Steubenville Chamber of Commerce in 1928. Mr. Holcombe opined that the "growth and development" of the Thermalaid quackery proved conclusively that it had rendered a real service to many people and therefore Mr. Holcombe would "gladly substantiate" what the concern had "done for humanity!" Other testimonials allegedly from physicians were published, but without any names or addresses.

Part of the advertising balldoo of the Thermalaid was the "gift" to purchasers of the device of a booklet entitled 'The Male Motor.' This was said to be by "Dr. M. Sayle Taylor

Sc.D., Ph.D., Sexologist." M. Sayle Taylor was the subject of an article in this department of THE JOURNAL March 12, 1932. Since that article appeared, M. Sayle Taylor has been much in the public ear over the radio as 'The Voice of Experience.' In the Bureau of Investigation article it was brought out that M. Sayle Taylor was at that time appearing in motion picture theaters in connection with films of an erotic character and at other times gave "stage presentations" in which he used "living models" and "human charts." The Chicago Tribune, in writing up one of Taylor's appearances in a local theater, stated that Taylor's "message is so appallingly crude and nastily nauseating that at first the stronger stomachs of the audience are inclined toward lusty laughter. However, they gradually succumb to the wizardry of his eloquence, until, at the end they are whipped into a frenzy of morbid sensationalism." At that point said the Tribune reporter, M. Sayle Taylor's high-powered salesmanship came into action, and he had for sale three paper pamphlets "dealing with the mating instinct and other problems appertaining thereto which were sold all for one little dollar bill." The pamphlets were passed through the audience, according to the Tribune's report not by ushers but by "usherettes of apparently immature years."

Two subsidiary pieces of quackery have also been explained by the Electro Thermal Company. One was a so-called medicated lubricant rejoicing in the name of "Iktlin" and sold for \$1.25 a tube, the other as might have been expected was an alleged vitamin concentrate sold under the name "Sim Mettle—Double 20 Formula" at \$5 a jar.

The Federal Trade Commission has ordered that the Electro Thermal Company cease and desist from making such claim either through the use of testimonials, newspaper or magazine advertisements, radio advertising, etc., as "That 65 per cent of all men past middle age have prostate trouble." That the Thermalaid is a "positive cure for any ailment." That the

Thermalaid "constitutes a competent treatment or cure for prostatitis" or for hypertrophy of the prostate or for constipation or hemorrhoids. Various other false claims that have been made by the Electro Thermal Company the Commission has ordered shall no longer be made.

While those who realize the pernicious character of the business of the Electro Thermal Company congratulate the Federal Trade Commission in having done a public service in issuing a Cease and Desist Order, one can but regret that this business, which is carried on wholly through the United States mails has not long before this been debarred from the use of the mails by the issuance of a fraud order.

Correspondence

VOCABULARY OF PHYSICIANS AND APTITUDE TESTS

To the Editor—Flack, discussing "Aptitude Tests for Medical Students" (THE JOURNAL, July 4 p. 61), mentions various factors that have turned the attention of the officers of medical schools toward the possibilities of aptitude tests in solving their problems. The tests employed include a scientific vocabulary test. Yoakum (reported by Twitchell, D. F. Report of Data Pertinent to the Problem of Selection of Medical Students *J. 4 Am. M. Coll.* 6:357-361 [Nov.] 1931) has experimented with an exclusively vocabulary and reading test in an endeavor to predict the success of students in later medical studies. After

Terms Encountered in Garrison's History of Medicine

adumbrated	theurgy	eidetics

polonaise	zany	gamlit
esoteric	menbitic	gerundive
hilastic	panada	thorama
laie	lurim	thuggee
metempsychois		diacoty

describing the results obtained thus far in a number of medical schools, Flack concludes that the aptitude tests have gone a long way toward solving the problem of selecting applicants to medical schools. Wechsler states that contrary to what one

would expect, the vocabulary test is one of the best tests of intelligence. In fact, it correlates more highly with mental age than any other single test on the Binet-Simon scale.

In scoring the responses, elegance of definition is disregarded; any correct meaning is acceptable. (A Textbook of Clinical Neurology, ed. 3, 1935)

If vocabulary is to be a measure of intelligence for future physicians, Garrison pays a graceful compliment to the medical man of this generation in his celebrated History of Medicine. In this great work one encounters all the words listed in the accompanying tabulation, in the order in which they are given here. Will not every physician on meeting these familiar terms in his leisure reading feel a glow of self-assurance and gain confidence that, had aptitude tests been applied in his student days, he would have scaled over them with the greatest of ease?

JOSEPH NASH, M.D. New York

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

DETERMINATION OF CARBON MONOXIDE IN AIR

To the Editor—What is the best practical method of testing the carbon monoxide content of a room? I have a patient whose room on the third floor opens toward a narrow alley in the open rear of a commercial garage. He seems to be affected by the gas. What percentage of carbon monoxide would be considered injurious? Please omit name. M.D. Louisiana

ANSWER—There are several methods of analysis by which small amounts of carbon monoxide in air can be determined accurately, all, however, necessitate elaborate apparatus or involve refined analytic procedures. The most practical measure under the circumstances is to examine the patient's blood for carbon monoxide hemoglobin. The blood sample should be drawn after the patient has had maximum exposure and while he is still in the contaminated air. Most of the carbon monoxide will leave the blood during two hours in fresh air. The percentage of carbon monoxide hemoglobin can be estimated conveniently by the method described by R. R. Sayers and W. P. Yant (Method for Determination of Monoxide in Blood and Air, U. S. Bureau of Mines, 1925, Technical Paper 373 abstracted in Peters, J. P., and Van Slyke, D. D., Quantitative Clinical Chemistry (Methods), Baltimore, Williams and Wilkins Company, 1932). Their procedure can also be used to make a fairly accurate approximation of the carbon monoxide in the air of the room. A red cell count is also recommended, as the assurance of a polycythemia will give further indication of chronic exposure to carbon monoxide.

One part of carbon monoxide in 10,000 parts of air is considered the maximum permissible concentration for prolonged exposure. But the percentage of carbon monoxide hemoglobin in the blood of the patient is a more significant value. If it exceeds 10 or 15 per cent, some physiologic effects may be observed.

PRESERVATION OF HUMAN IMMUNE SERUMS

To the Editor—I am prepared to make serums from convalescent scarlet fever cases but would like your opinion as to the proper preservative and how long this may be kept in refrigeration. I should like any further information that you may give me on this subject. Kindly omit name.

M.D. New Mexico

ANSWER—Four-tenths per cent phenol or tricresol has been used for many years for serums generally. This amount is recommended by the U. S. Public Health Service. The preservative is mixed with an equal part of ether before addition to the serum. Merthiolate and metaphen have been used, usually in a concentration of 1:5,000. Other organic mercurials may be employed. Some have the disadvantage of adding some color to the preparation. The National Institute of Health requires specimens specific nine months from date of preparation to expiration when the serum is kept constantly at 0.4 C. Utmost aseptic precautions during processing and adequate sterility tests both

on the individual samples and on the final pool of serum, are essential. It would be advisable to follow rigidly the requirements of the National Institute of Health in the preparation of human immune serums.

TREATMENT OF MENINGITIS

To the Editor—Following is a report of a case of cerebrospinal meningitis with a fatal outcome. I will appreciate your criticism of my plan of therapy and any suggestions you may have to offer. I first saw the patient a youth aged 17 years July 4 at 5 p. m. He had been ill with severe headache for four days. His neck had been sore stiff and acutely retracted since the morning before about thirty hours. I immediately did a spinal tap at which time 45 cc. of cloudy spinal fluid was gradually allowed to drain. Thirty cc. of Mulford's antimeningococcus serum was introduced into the spinal column by the gravity method. Also 30 cc. was given intravenously. The conjunctival test for sensitivity was previously carried out and was apparently negative. At this time the patient's temperature was 103 the pulse 120 the spinal fluid cell count 2350. He was rational. On the morning of July 5 a spinal tap was again done and 40 cc. of fluid was withdrawn. 25 cc. of Mulford's serum given intraspinally and 20 cc. intravenously. That night ten hours later 30 cc. of serum was given intravenously and 15 cc. intramuscularly. By the next morning July 6 I had been able to secure meningococcus antitoxin of which I had read and approved. A spinal tap was done and 40 cc. of spinal fluid was withdrawn and 20 cc. of antitoxin Parke Davis & Co. was given intraspinally and 40 cc. intravenously. At this time there had been no noticeable change in the patient's condition since I first saw him. The case appeared hopeless. Ten hours later he received 60 cc. of antitoxin intravenously. A spinal tap was done the morning of July 7. 45 cc. being obtained and 60 cc. more antitoxin being given intravenously. Ten hours later 60 cc. more was given intravenously. I had not as yet noticed any appreciable change in the patient's condition. The morning of July 8 I found the patient free of headache his neck was not nearly so stiff and he could move it about 15 degrees without pain. He said he felt all right. His temperature was 101.5 the pulse 104. A spinal tap yielded 40 cc. of fluid. 60 cc. of antitoxin was given intravenously. He appeared better. Ten hours later 30 cc. more antitoxin was given intravenously. The morning of July 9 a spinal tap yielded 35 cc. of fluid and 30 cc. of antitoxin was given intravenously. A cell count of the spinal fluid was 900. The patient was much improved. Ten hours later 30 cc. of antitoxin was given intravenously with the patient still improved. The morning of July 10 the patient could move his head about 40 degrees. He had no complaint and no headache. His neck felt all right there was no delirium and he had been resting and sleeping well. It seemed to me that he would recover. As a prophylactic measure against reaction I had been giving him 0.5 cc. of 1:1000 epinephrine hydrochloride subcutaneously prior to each intravenous injection both of serum and antitoxin. The patient had had morphine sulfate one fourth grain (0.016 Gm.) when needed for pain or restlessness from the beginning which averaged about every six hours. The morning of July 10 his temperature was 100.5. He was in good spirits there was no headache the neck was more relaxed than ever and I felt that recovery was imminent. A spinal tap yielded 30 cc. of fluid. 30 cc. of antitoxin was given intravenously. About one hour after I left the patient he became sleepy and cyanotic and wished to be fanned as fast as possible. According to his nurse he fell into a restless sleep breathing became deep and labored and he died one and one-half hours after I gave him his last dose of antitoxin. I am asking you to review this entire case closely and to give me a detailed report on what you believe to have caused the patient to die. He was getting better by every criterion by which I know to gauge such a case. I know of no reason for such a sudden death. Previously I have treated five cases of meningococcus meningitis. They were treated with the serum and three of the patients lived. I have never been so surprised or disheartened at the outcome of such a case as I was with this one. Please criticize my therapy closely. If you can enlighten me as to my shortcomings in treating this case or give me any information that might be of benefit in treating subsequent cases I shall be grateful.

M D Tennessee

ANSWER—It is apparent that the patient received good treatment. It seems probable that death was due to either pulmonary embolism or pulmonary edema. Such accidents have been known to occur in connection with the treatment of patients by the intravenous route.

The following suggestions are offered for treating meningococcus patients. Administer meningococcus antitoxin or antimeningococcus serum should you prefer the latter remedy, in larger doses intravenously. Usually 100,000 units of the antitoxin or 200 cc. of antimeningococcus serum is not too much for an initial dose which may possibly consist of all that is required. The remedy however when given intravenously should be diluted in approximately twice its volume. For a diluent, 10 per cent dextrose in physiologic solution of sodium chloride has been found to be satisfactory. To this mixture from 0.6 to 1 cc. of epinephrine should be added. The mixture is administered slowly at body temperature by the gravity method.

Howe believes that meningococcus meningitis patients respond more satisfactorily to intravenous treatment when there is no intraspinal medication. Lumbar punctures may be made when

deemed advisable for the purpose of relieving pressure and checking on the progress the patient is making as a result of intravenous therapy.

Some clinicians with broad experience in the treatment of meningococcus meningitis are strongly opposed to the use of morphine for patients with such infections. As a matter of practical observation it has been noted that meningococcus meningitis patients who are given morphine do not always progress well. It is possible that morphine in these cases increases cerebral edema. Some other sedative is preferable.

PREVENTION OF IMPOTENCE

To the Editor—I have had under observation a man, aged 21 Jewish, whose main complaint is sluggishness in obtaining an erection under conditions of sexual excitement. He says that if sufficient erection is secured for insertion he has a premature orgasm or none at all. If the sexual act is repeated the conditions of his sexual lag or precocity assert themselves and the act is practically normal. Examination reveals evidence of a mild hyperthyroidism—palpable gland very slight tremor emotional instability continuously sweating warm hands weight loss of 10 pounds (4.5 Kg.) pulse from 90 to 100 blood pressure 140 systolic 85 diastolic ruddy face and a basal metabolic rate of plus 15 and plus 10. His appetite is good but not ravenous and he states that he does not have heart consciousness. The prostate and external genitalia are those of a healthy male. The urine is cloudy with phosphates (heavy) but is otherwise negative. Blood examination reveals 100 per cent hemoglobin 5 050 000 erythrocytes and 9 600 leukocytes. The differential count is normal. The semen has not been studied. Other physicians have given him prostatic massage and testicular extracts he had a course of aututrin-S consisting of twenty 1 cc. doses with subjective decrease in nervousness weight gain pulse reduction to 80 and blood pressure fall to 125/75 (weekly readings). He was given iodine after the aututrin course which further decreased his nervousness and decreased the sweating. The sexual complaints persist. I recently had occasion to see a second patient complaining of almost the same sexual difficulties including the improvement on repetition of the sexual act. This man had a pronounced hyperthyroidism. Thyroidectomy is obviously indicated in the second case but the symptoms in the first case are mild so far as the thyrotoxicosis is concerned and one hesitates to advise surgery on the thyroid from that angle per se—the patient primarily wants relief from his sexual difficulties. The psychic element must be weighed in relation to his sexual complaints and this thyroidectomy might or might not improve. I am open for suggestions and advice. Please omit name and address.

M D., Illinois.

ANSWER.—The history given is the usual one in cases of oncoming impotence, namely, first rapid ejaculation then premature ejaculation, and finally more or less inability to obtain any erection at all. Although the statement is made that the prostate feels normal, in many of these cases an examination of the prostatic urethra with the cysto-urethroscope will reveal more or less congestion, especially about the region of the verumontanum, which may or may not be enlarged. It is not necessary to find gross pathologic change in the prostatic urethra, such as tumors, as the congestion just referred to is amply sufficient to cause the symptoms. No local anesthetic should be employed, as this might mask the congestion. The etiologic factor most often found is the indulgence in ungratified sexual excitements, such as excessive spooning with artificial holding back of ejaculation. On account of the marked congestion in the prostatic urethra, the reflex act of coitus takes place almost at once or soon after the increased congestion of sexual excitement. After this condition has lasted some time the muscles and nerves and nerve centers connected with the sexual act become exhausted and erection fails or is very incomplete.

Orchic extracts as well as aututrin-S can have no effect in these cases, as even normally they have no influence on the process of erection and ejaculation. For the same reason the examination of a condom specimen, while interesting for other reasons, cannot give information regarding the process of erection or ejaculation.

The treatment consists in first getting rid of the local congestions before starting any stimulating treatment. It is also absolutely important to interdict spooning or other ungratified sexual excitements. The prostate should be gently massaged and instillations of weak silver nitrate solutions (from 1:3000 to 1:500) should be given into the prostatic urethra with the Bangs sound syringe about every five days. Generally in about six treatments the congestions are removed and often the patient is well. If not, however this shows that the muscles and nerves have been weakened, and stimulating treatment is in order. For this purpose the sinusoidal-faradic current of moderate rapidity and as strong as the patient can bear without any pain has been suggested. One cable is connected with a rectal electrode and the other with a wet sponge electrode applied to the perineum and the current allowed to pass for about ten minutes. Treatments may be given every four days.

TREATMENT OF MENSTRUAL IRREGULARITY
AND STERILITY

To the Editor—A woman aged 23 complains of menstrual irregularity and secondary sterility. Her periods began at 13 years of age and were always regular until a year after her marriage at which time she had a spontaneous miscarriage at about two or three months pregnancy. No fetus was found but a piece of (or the entire) placenta was extruded and examined microscopically and found to be normal. Since this time for the past year her periods have been irregular varying from forty to seventy days apart. Despite lack of attempts at contraception she has not become pregnant though she is very eager to do so. She is 62 inches (157.5 cm) tall and weighs 145 pounds (66 Kg). A thorough physical examination yields no clues as to the possible reason for her menstrual disturbance or secondary sterility. I have used amniotin, theelin and progynon B repeatedly and frequently with no other effect than that of slightly clearing her mild acne. For a basal metabolism rate of minus 11 I have used 1 grain (0.65 Gm) of thyroid twice a day for a period of three months with no effect on the pulse rate or weight. A rigid low calory high protein diet with 3 mg of thyroxine hypodermically twice a week has also done nothing to her weight. There is a tendency to girdle distribution of fat with heavy thighs. A Huhner test shows that her vaginal secretions quickly (one hour) kill the spermatozoa of her husband despite the fact that these are very numerous motile and by themselves long living (thirty hours on a glass slide rimmed with petrolatum and at room temperature). There is a strong libido and desire for impregnation. The secondary sexual characteristics are very well developed. At the present time she has not had her period for seventy four days and is nauseated but does not vomit. The Friedmann test is negative and examination does not even lead me to be suspicious of pregnancy. I am at a loss as to what to do in this case and would greatly appreciate any suggestions you may have to offer. If you print this letter will you please omit name? M D New Jersey

ANSWER—There are cases in which after a miscarriage a curettage is performed too radically with the result of entirely destroying the endometrium, resulting in amenorrhea and sterility. There is, however, no mention of such an operation in this case. In the absence of such a history it must be concluded that the condition is endocrine in origin. There are many factors in the history which distinctly point to such a diagnosis. The death of the spermatozoa within the vagina in an hour does not indicate anything wrong, as this condition is frequently found in normal cases. It is more important to note whether the spermatozoa reach within the cervix and remain alive there or are killed there or are stuck in the cervical mucus as this is the main diagnostic significance of the Huhner test.

Treatment should be directed on endocrine principles but is still wholly experimental. Most standard preparations state the number of rat units contained. They should be given in fairly large doses. In addition, an outdoor life with plenty of sunshine is indicated.

PAROXYSMAL TACHYCARDIA

To the Editor—A business man aged 37 has had repeated attacks of paroxysmal auricular tachycardia for thirteen years with increasing frequency now they occur about once or twice a month. They are ushered in suddenly and violently the pulse and apical rate rising to about 200 per minute. These last from two to three hours and are terminated by induced vomiting. Vagal or orbital pressure has no effect. The Wassermann reaction is negative. The patient has an aortic and mitral insufficiency with percussable cardiac enlargement. The cardiac reserve determined by exercise is low. Compensation is still established. Would you advise quinidine sulfate in the presence of this endocarditis? Would you advise choline? How is this administered? Would you give digitalis concomitantly or previous to quinidine medication? Quinidine 3 grains (0.2 Gm) three times a day does not help. Should I increase the dose? Please omit name? M D New York.

ANSWER—It is assumed that this case with a negative Wassermann reaction is one of rheumatic origin. Lesions causing aortic regurgitation are less apt to create disturbances of rhythm than those of the mitral endocardium. A postmortem examination of hearts in cases of mitral stenosis makes this easy to understand. The onset of paroxysmal tachycardia in a patient who has had rheumatic fever and who subsequently shows merely a systolic mitral murmur should make one very suspicious of mitral stenosis. It has been the experience of many that the intervals between attacks of paroxysmal tachycardia tend to shorten until, as Lewis pointed out some years ago one comes that persists in spite of all our efforts.

Digitalis or quinidine sulfate may be used during the intervals. These drugs should be tried separately, giving the first place to digitalis which may be used at the rate of 0.1 Gm a day over a period of several months and the dose can be varied according to the effect on the cardiac rate. It is more valuable than quinidine sulfate, which may be tried if digitalis is unsuccessful. The patient has been given quinidine and since he tolerates it well it may be administered in larger daily doses. Quinidine when well borne may be given for auricular fibrillation or auricular paroxysmal tachycardia up to 18 Gm a day for three or four days, after which the patient might take 0.2 Gm two or three times daily. The usual precautions with

regard to the use of quinidine in cases of long standing disturbances of auricular rhythm must be regarded. Quinidine has small value in stopping an acute attack.

Steff and Schliephake in 1925 reported full and almost instantaneous control of paroxysmal tachycardia by using 0.5 cc of a 5 per cent solution of choline chloride intramuscularly. More recently this drug under the name of Mecholin (Merck) has been strongly recommended for intramuscular injection during the attack. It comes in dry ampules of 0.025, 0.1 and 1 Gm. Calcium gluconate has recently been used during the attacks. It comes in 10 cc ampules, which may be injected into the muscle. It has also been given in the intervals in wafers of 15 Gm each, which the patient can use himself. It is interesting that the patient's attacks cease with induced vomiting. One cardiologist uses only ipecac to induce vomiting and in that way ends the acute attack. Lunigo many years ago advised emetine for the same purpose.

PELVIC ENDOMETRIOSIS

To the Editor—An unmarried woman aged 38 who weighs 120 pounds (54 kg) is 5 feet 7 inches (170 cm) tall and whose parents, brothers and sisters are healthy and normal has taught school most of her life since graduation and her habits are excellent. The menstrual period began at 13 occurs every twenty-eight days and lasts from five to seven days. On the first few days it is always very free. Twelve years ago she had an acutely inflamed appendix removed. Recovery was uneventful. She had no serious illness, accidents or other operations until eight months ago. About five years ago she began to have pain in her right shoulder. The pain appeared the first day of the menstrual cycle the second day was better and at the end of the cycle appeared again and lasted from seven to ten days and was very severe. This pain has increased in severity until now it almost incapacitates the patient. The pain radiates around the region midway of the clavicle and first rib. The patient describes it as being pain deep in. At no other time of the month does this bother her. Headache usually accompanies the pain. Eight months ago on examination it was found that she had a mass in each side of the pelvis the uterus was firmly fixed. At operation it was found that each ovary had undergone cystic degeneration and tumor formation. The tumor was filled with a chocolate bloody substance, multilobed in character. The same trouble had affected the ovaries and most of the ovarian tissue was destroyed and it was hard to eradicate the tumor and contents and leave any ovarian tissue. However this was done and the patient has I think her usual amount of ovarian substance. At that time a subtotal hysterectomy was done because of some small fibroids on the uterus. All the uterine tissue possible was left. Now at each menstrual period the patient menstruates a very little with no pain or cramping which was present before. However she has the same unusual annoying pain in her right shoulder and so far as I can see the pelvic condition is corrected. The patient has never impressed me as typically neurotic. Her teeth are good and the tonsils are gone. There is no evidence of infection around the head any place. The urine is normal. The Wassermann reaction is negative. Her vision is good. There is no other evidence of a pathologic condition any place in her body. The unusual feature about this case is the persistent pain in the shoulder with the accompanying headache which pain and headache appear at the end of the period and last for seven or ten days. I would appreciate some reference data or other information which you no doubt will be able to give.

M D Arkansas

ANSWER—This patient evidently had pelvic endometriosis and some of the disease may still persist. As is often the case, there were associated uterine fibroids.

In the presence of extensive pathologic change, such as here described radical surgery is usually required to effect a permanent cure. If the endometriosis is extensive and the ovaries are not removed, the disease tends to progress, slowly but continuously, until after the menopause. With complete removal of both ovaries all endometriomatous lesions atrophy and disappear. (References: Sampson, *The Life History of Ovarian Hematomas of Endometrial Type*, *Tr Am Gynec Soc* 1922, pp 47-56; Keene and Kimbrough, *Endometriosis*, *Obstetrics and Gynecology* edited by Curtis, Philadelphia W B Saunders Company 3 338, 1933.)

Gaseous distention of the bowel or free gas in the peritoneal cavity (such as occurs at the time of transuterine insufflation of the fallopian tubes) is the most common cause of shoulder pain. In this case, pelvic adhesions with flatulence probably cause the right shoulder pain.

Discomfort is often more pronounced in such patients at or near the time of menstruation because the patient is at low ebb at such times is more sensitive to pain, and is then more disposed to constipation and abdominal distention.

When the shoulder pain is acute, immediate temporary relief may be obtained by assuming a recumbent position, with the head lower than the pelvis.

Dietetic measures directed to the relief of flatulence are indicated. The patient should eat slowly and temperately and should avoid rough foods, candy, pastry and potatoes. Elimination from the bowels should be free.

PAIN IN SPINE AFTER SPINAL ANESTHESIA

To the Editor—A woman aged 32, of a highly neurotic nature, had a major abdominal operation about fifteen years ago for double salpingitis and removal of the appendix. She made a rather poor recovery in a nervous way and complained of abdominal distress following this operation yet general examination revealed but little concerning her physical condition other than a marked neurosis. About five years later she was operated on again in another town and I have not been able to find out definitely just what was done at that time but her symptoms of general neurosis, obstinate constipation, dysmenorrhea and complaint of general discomfort continued the same, yet her general physical appearance during all this time was that of a well nourished rather obese individual. No laboratory examination revealed any definite pathologic change. In June 1934 she was sent to a charity hospital for general examination and such treatment as was indicated. The laboratory and roentgen examination made there revealed nothing of consequence but she was operated on under spinal anesthesia and many abdominal adhesions were found and removed. (From such information as I have been able to get I think this was principally what was done at the time of the second operation.) She reports that immediately after the effect of the anesthesia passed off she began to have considerable pain about the region of the second and third lumbar vertebrae. (She was complaining much of this pain when she came home from the hospital two weeks later.) This pain has continued to date and she pretends to have much tenderness on pressure at about the region of the second and third lumbar vertebrae and says that the pain refers down the posterior and outer surface of each thigh also that the pressure on the lumbar region mentioned increases the pain in her head. The question in my mind is: Did the spinal anesthesia create a fibrosis of the cord that is making the pain or is this a generalized neurosis? I would appreciate your opinion and especially the suggestion of a treatment; as I have been unable to accomplish much in the way of relief of the patient.

M D Nebraska

ANSWER—Probably the diagnosis of neurosis, made fifteen years ago, is correct. Without any evidence of definite neurologic manifestations it is most unlikely that one could be dealing with fibrosis of the spinal cord. Spinal anesthesia probably had no specific effect on the present complaint but the reaction is one that is frequently seen in cases of this type following any surgical procedure. The question of treatment is a difficult one and the decision must depend entirely on the intelligence of the patient and on her cooperation with the physician. One of two courses might be pursued. Either her problem might be frankly discussed with her, causing her to realize the nature of her trouble, or she might go to a good sanatorium or some institution where cases of this type are often successfully treated. This patient represents a type of case in which it is well to avoid the use of a spinal anesthetic, because frequently the patient complains afterward about any one of a number of things, even resenting the fact that consciousness was maintained during the operation. There was no mention of trauma during the administration of the spinal anesthetic, which in itself might become a factor that could have a bearing in such a case.

HYPERTENSIVE DISEASE AND PREGNANCY

To the Editor—For the past year I have been taking care of a woman aged 34 with a marked hypertension ranging from 200 to 230 mm. of mercury systolic and from 130 to 140 diastolic. About eight months ago she miscarried a five months pregnancy and thereafter for a few months felt a great deal better her blood pressure falling to 180 systolic and 110 diastolic. Her headaches have been greatly relieved by correction of a refractive error and treatment of a sinus condition. I have prescribed phenobarbital and theohromine-phenobarbital and have also used bismuth subnitrate in the recommended doses with no effect on the blood pressure. I have doubts as to the value of the hypotensive drugs and have not used them consistently. There does not appear to be kidney damage or myocardial insufficiency as yet. Can you suggest a rationale of treatment? What would the prognosis be? Would repeated venesections be of value? Please omit name.

M D Pennsylvania

ANSWER—It is not clear from the query how severe a hypertension existed prior to the patient's pregnancy. If the diastolic tension had been persistently in the neighborhood of 110 to 120 prior to pregnancy the patient should not have been permitted to go on to the almost inevitable miscarriage at five months. It has been emphasized repeatedly (Adair, F. L. and Stegitz, E. J. *Obstetric Medicine*, Philadelphia: Lea & Febiger, 1934, chapters XXII and XXVIII) that pre-existent hypertensive arterial disease and/or nephritis are invariably greatly exacerbated by pregnancy and that this exacerbation persists permanently. The longer the pregnant state continues the more severe and irreparable is the permanent damage. Unquestionably this is just what occurred in the present instance there being a transient incomplete diminution in the intensity of the hypertension because of the release from the intoxications incident to the pregnancy. It is doubtful whether any medication will prove of much value here, for it is probable that in this instance arteriolar sclerotic changes have already occurred and such damage is irrevocable, irreparable and nonamenable to therapy. The vasodilator drugs are too mild to overcome the

intense intoxications responsible for the hypertension. It must be emphasized that the high blood pressure per se is but a symptom of this intoxication. Bismuth subnitrate and the barbiturates are ineffective in the presence of such active etiological irritation.

Pregnancy causes a great change in the character of hypertensive arterial disease. A slowly progressive, relatively mild disturbance becomes rapidly aggressive and destructive. Qualitatively the disease is unaltered but quantitatively it is tremendously accelerated in its course. The youth of the patient also tends to more rapid progression or "malignant hypertension."

The query states that "there does not appear to be kidney damage or myocardial insufficiency as yet." One may probably take this to mean that the patient has no cardiac embarrassment or failure and that the urine is relatively free of protein and casts, but it is unjustified to say that there is no renal or cardiac impairment. In hypertensive arterial disease there is a long period of gradual reduction of the functional reserve of both the heart and the kidneys. It is a justified clinical concept to assume that such injury occurs invariably. Study of the renal functional reserve, especially with the test procedures that involve stress, such as the renal concentration test and the urea clearance test, would most certainly reveal considerable reduction of the renal reserve. So long as the renal efficiency suffices to care for the daily and usual requirements, there will be no true renal symptoms or hyperazotemia, but a great depletion of the margin of safety must occur before such decompensation. Such lowered reserve is essentially asymptomatic. The query gives no clue as to the possible etiology of the original hypertensive disease and the nephritis, which may be assumed to have existed prior to the tragically unfortunate pregnancy. For this one must dig carefully and thoroughly into the past history of the patient: the nephritic sequelae of scarlet fever often remain "latent" and unsuspected for years to appear later as a severe renal failure or "uremia." This was recently emphasized by F. D. Murphy, John Grill and G. F. Movon (*Acute Diffuse Glomerular Nephritis*, *Arch. Int. Med.* 54: 483 [Oct.] 1934).

The prognosis is bad. The life expectancy is but a few years. Therapy of many kinds has proved of little avail. Repeated venesections are decidedly contraindicated. It is more than probable that this patient has developed or will develop the highly resistant form of secondary anemia characteristic of nephritis. Repeated transfusions would be more in order although the benefit from them is but transient.

INDUCTION OF PREMATURE LABOR

To the Editor—Kindly discuss induction of premature labor from the standpoint of indications. A primipara, aged 21 with excellent personal and family history, had a perfectly normal pregnancy except that the weight gain was about 35 pounds (16 Kg.) from 129 to 164 (58.5 to 74.4 Kg.). Her height is 5 feet 7 inches (170 cm.). The breech position was diagnosed by the usual means and roentgen examination. There were pressure symptoms—shortness of breath and a tight feeling rather much in evidence but decreased about a week before the date of the expected delivery. Eight days before the calculated date for delivery labor was induced. The patient went to the hospital the same morning and delivery was accomplished by 6 p. m. A small tear necessitated one stitch. The mother's condition was excellent at all times during delivery and has been since. No instruments were used. The mother has no remembrance of labor. The child weighed 9 pounds 13 ounces (4 450 Gm.). It was born blue and did not breathe for half an hour. Then it breathed only periodically and as the result of much effort by attendants. Stimulants, artificial respiration, insufflation and carbon dioxide and oxygen were administered. It lived about thirty-six hours. Autopsy showed laceration of the superior longitudinal sinus as the cause of the condition following birth and of death. Is it considered good practice nowadays to induce labor prematurely in breech presentations when breech position is the only abnormality? If so, how long before the calculated date of delivery? Kindly omit name.

M D California

ANSWER—The indications for the induction of premature labor have changed a great deal as the result largely of the increased safety and incidence of cesarean section. There are some who have advocated and do advocate the induction of labor on a predetermined date but such a routine indication is not generally accepted by obstetricians. As a rule the present day indication for inducing premature labor are maternal rather than fetal and include such conditions as toxemia and placenta praevia which threaten the mother's life.

An induced labor is not a normal labor though it may be so essentially if the time of induction is at term. Consequently the risk to the mother is greater and the fetus is exposed to added hazard which is increased with the degree of prematurity. In the case cited the child was very large which also increased the risk, especially with a breech position in a primipara.

woman. The parturient canal must have been ample to permit of the delivery of such a large fetus without operative intervention. Death was obviously due to intracranial injury caused by the delivery of the aftercoming head. Whether this was due to resistance of the soft or bony parts of the birth canal is not apparent from the query.

It is fair to say that the induction of labor for a breech position is not an established procedure at the present time. One is doubtless justified, especially in a primiparous woman in attempting to perform an external version and carrying it out if it is easy to accomplish.

The management of a breech labor is important, and the mechanism should never be hurried. Forceps to the aftercoming head is justifiable and may facilitate delivery of the head, prevent suffocation, and avoid injury to the central nervous system especially the medulla and the cervical cord.

X RAY THERAPY IN HYPERTHYROIDISM

To the Editor—Will you please let me know what the contraindications are for high voltage x ray therapy in hyperthyroidism? From the trend of recent literature I can find little reason not to recommend this form of treatment in preference to surgery since it seems to be efficient in a high percentage of cases and is free from danger. The patient in whom I am particularly interested is over 30 years of age and the basal metabolic rate is plus 40 per cent checked. He has received no iodine therapy. Symptoms of tachycardia and tremor have existed for three months. Please give medical references on this subject. Please omit name.

MD New York

ANSWER—The contraindications to roentgen therapy for hyperthyroidism revolve around the severity of the condition. If hyperthyroidism is marked and if its symptoms are pronounced, the need for measures, both medical and surgical to improve the patient's situation as rapidly as possible is evident. On the whole, combined medical and surgical treatment, when given by some one with exceptional skill and experience, yields a higher percentage of satisfactory results than any other single method of treatment. On the other hand, if the symptoms are of moderate severity and urgent measures are not required, radiotherapy may well be tried. Such a trial involves repeated exposure of the thyroid and upper mediastinal regions to a moderate quantitative dose of roentgen rays. If, after such treatment has been continued for four months, the condition of the patient is still unsatisfactory, the advisability of continuing radiotherapy seems doubtful.

Specific references to the contraindications to radiotherapy are not available. The literature of radiotherapy for hyperthyroidism is so extensive that only the most important articles within the last few years can be included.

MEOPAUSAL DISTURBANCE IN YOUNG WOMAN

To the Editor—A woman aged 30, suffered from dysmenorrhea for fourteen years which began three years after the onset of menstruation. The periods were regular and lasted five days with pain of such intensity as to require morphine for relief. The patient had to remain in bed for two days of each menstrual period. Eight months ago it was considered advisable to remove the uterus for relief of symptoms. At operation the right ovary was found to be cystic and was also removed. Since then at intervals coinciding with the former menstrual periods the patient has complained of headaches, hot flushes, irritability and nervous tension. To use the patient's own words she feels as though she would go to pieces if she did not hold herself in check. This last symptom is of three days duration and has appeared at a time that would be equivalent to a week before menstruation. It is causing the patient considerable worry since it is interfering with her work as a commercial chemist. She finds herself forced to sit down for fifteen minutes to calm herself sufficiently to continue her work. Aside from the symptoms mentioned the patient seems to be in good health. I would value a suggestion as to treatment. Kindly omit name.

MD, Georgia.

ANSWER—Even though presumably one ovary was left in place, the patient seems to be suffering from menopausal disturbances. In a large number of cases, complete or partial relief from the distressing symptoms can be obtained from the use of estrogenic substance. The best way to administer this is by the hypodermic route and the patient can easily be taught how to give the hypodermics to herself, using the thighs for the sites of injection. The commercial preparations generally used in this country are ammotin (Squibb) and theelin (Parke Davis & Co). One ampule containing 2,000 international units of estrogenic substance should be given daily. If for some reason, the patient cannot take a hypodermic injection each day, oral preparations of estrogenic substance may be combined with the hypodermic preparations. The oral products are known as theelin capsules (Parke, Davis & Co) and ammotin capsules (Squibb). The dose administered by mouth should be about five times the hypodermic dose. It is best to begin with large doses of these substances taken daily and then cut down the amounts as the symptoms subside. After a few weeks the patient will learn just how much estrogenic substance is necessary to relieve most of the distressing symptoms. In most cases these substances must be taken for many months and generally up to about two years. In this case because the patient is only 30 years old, she most likely will have to use these preparations for a longer time. She may obtain the desired relief by taking the estrogenic substance only during the seven or ten days each month that would correspond to the premenstrual and menstrual periods. This can be determined only by experiment. In addition to estrogenic substance it is advisable to prescribe the daily or almost daily use of small doses of a mild sedative. This should be discontinued as soon as feasible.

PAGET'S DISEASE

To the Editor—A man aged 60 a veteran is suffering, from Paget's disease (according to x ray observations in the right ankle). The condition sometimes is painful, and the patient walks occasionally with a limp. The trouble started during border service in 1916. The patient always has been irritable is sort of a lone worker and doesn't mingle well with others. He is a college graduate, also an M D married and the father of six healthy children. There is no history of venereal disease. At present he is wearing protection in the heel of the shoe and is sparing the foot all he can. Please omit name.

MD Massachusetts

ANSWER—In general the treatment of Paget's disease of the bone has been most unsatisfactory except for the orthopedic measures. High doses of viosterol combined with intravenous calcium administration have apparently been used with some degree of success. Daily intravenous injections of from 5 to 10 cc of calcium gluconate for thirty days has been recommended. After an interval of fifteen days a new series of injections for another thirty days may be given.

LIGHT NEEDED FOR STUDY

To the Editor—This letter comes to you as an inquiry regarding school board work and for the benefit of the school children. Do you have or can you get information regarding the necessary foot candle lights required to give school children a negative eyestrain? The light companies in our district have been testing the lights in various school rooms and with the apparatus that they have the lighting seems inadequate although reading is not difficult with the present lighting system. It has been stated by the light company that from 15 to 20 foot candles is the proper amount of light required for study. I would appreciate your sending me any data that you may have regarding this matter.

G F Love MD, Braddock Pa

ANSWER—The amount of light needed for study without fatigue is from 15 to 20 foot candles. The Chicago public schools are now being tested and equipped to supply 18 foot candles.

District of Columbia July Examination

Mr J P Foley, assistant secretary, Commission on Licensure, reports the written examination held in Washington July 13-14, 1936. The examination covered 10 subjects and included 60 questions. An average of 75 per cent was required to pass. Twenty-four candidates were examined 23 of whom passed and 1 failed. The following schools were represented

School	PASSED	Year Grad	Per Cent
George Washington University School of Medicine	(1932)	(1932)	76.6
(1935) 781 808 826 828 829 836 838 838			
84 845 863 88			
Georgetown University School of Medicine	(1935)	(1935)	75.6
771 78 785 79 2 821 827 837			
Ohio State University College of Medicine	(1922)	(1922)	79.3
University of Virginia Department of Medicine	(1933)	(1933)	84.4
School	FAILED	Year Grad	Per Cent
Georgetown University School of Medicine	(1935)	(1935)	75

Six physicians were licensed by endorsement on April 6 and July 27. The following schools were represented

School	LICENSED BY ENDORSEMENT	Year Grad	Per Cent
College of Medical Evangelists	(1933)	(1933)	76.6
University of Maryland School of Medicine and College of Physicians and Surgeons	(1933)	(1933)	76.6

Book Notices

The Balanced Diet By Logan Clendenen, M.D. Professor of Clinical Medicine, University of Kansas. Cloth. Price \$1.50. Pp 207 with 15 illustrations. New York & London: D. Appleton Century Company, Incorporated 1936.

This book represents a popular presentation of the essential facts of nutrition. Part I deals with the requirements of an adequate diet. It considers briefly the functions of carbohydrates, proteins, fats, water, inorganic minerals and the vitamins, it discusses the physiologic effect of spices, condiments and beverages, and summarizes the contribution to the diet made by each of the common food groups: milk, eggs, bread and so on. Part II outlines the type of diet suited to different ages, the principles and procedures for diet in various diseases, and a chapter each is devoted to food fads and the economics of food. Tables of food composition and of common weights and measures are included. The content and style of the book suggest that it was written for the intelligent layman, and in large measure the volume is suited to this end. The language for the most part is simple, the style is interesting and direct, and the illustrations are pertinent and effective. Yet, like most people who attempt popular writing, the author frequently forgets his audience and talks over their heads to the physician or other scientifically trained person whom he apparently sees lurking in the background. In this vein he discusses the historical contribution of Claude Bernard, Liebig and Hoppe-Seyler, gives a technical description of the bomb calorimeter, uses such terms as "anhydrides of amino acids," "anaerobic conditions," "purine and xanthine bodies," and throws in for good measure the structural formula for an amino acid. This is not for long, however, for he soon remembers his lay audience and reverts again to his simple, effective presentation of essential nutrition material. It is unfortunate that in not a few instances some of the material included is at least by implication inaccurate or misleading. An illustration of this is found in the discussion of bread (p 91). The average person would interpret the discussion to imply that white bread is a well balanced food, since it is stated that it "contains vitamins A, B, and G, appreciable amounts of calcium, potassium, sodium, phosphorus, chlorine, sulfur and iron" and "goes well with other foods, supplementing their deficiencies." As a matter of fact, bread contributes chiefly calories and protein to the diet and (unless made of milk) the content of minerals and vitamins is so low as to be negligible when considered in relation to the body's need of these materials and in comparison with their abundance in other foods. There are, moreover, other sections in the text where the lay reader would be misled with respect to important dietary matters. Especially to commend to the perusal of the layman (and even the physician) are the discussion of what is a balanced diet in chapter I and the chapter on food fads. The doctrine of common sense in eating and the appropriate use of knowledge of nutrition in practical everyday life are here set forth with remarkable wisdom and clarity. As previously indicated, the style of the text and its graphic method of presentation are worthy of note. To the physician and the nutritionist the book will indeed be valuable chiefly for the many suggestions it affords of how scientific material can be presented in simple and graphic form.

Syphilis and Its Treatment. By William A. Hinton, M.D. Cloth. Price \$3.50. Pp 321. New York: Macmillan Company 1936.

This book is nearly valueless for medical students and physicians. A third is devoted to a wholly inadequate description of the clinical aspects of syphilis of which the weakest sections are those on the two most frequent and important late manifestations, cardiovascular and neurosyphilis. A hundred pages is given to a discussion of treatment, of which only that part limited to early syphilis is satisfactory. In opposition to experts the world over, the author feels that latent syphilis should usually be allowed to go without treatment until late lesions develop, ignoring the fact that all patients with late syphilis pass through a latent stage, during which adequate treatment will prevent late manifestations. For all forms of late syphilis, including cardiovascular syphilis and neurosyphilis, a standard form of treatment utilizing an arsphenamine, a bismuth com-

pound, mercury, and potassium iodide is proposed. He advises this plan of treatment even for dementia paralytica and states his opinion (which is in contrast to that of other observers) that the value of such special methods of treatment as tryparsamide, malaria and other forms of artificial fever have not yet been proved. A physician who attempts to treat patients with late syphilis by Hinton's methods will not only do them less than justice but subject many of them to grave danger from syphilis or its inadequate treatment.

The book is filled with statements with which other authorities do not agree. To cite only a few: *Spirochaeta pallida* may be grown by Noguchi's method (p 9), the quantitative titration of serum is valueless, since some serums give a zone phenomenon (p 29), the clinical diagnosis of primary syphilis is usually easy (p 42), symptomless infection is usually due to seminal transmission of the virus (p 81), the Hinton test usually persists for a lifetime in untreated late syphilis, while "most of the current Wassermann tests and the less sensitive flocculation tests . . . gradually grow weaker and become negative in five to ten years in perhaps half the cases" (p 84), trauma has little or no influence in the production of late syphilitic lesions (p 86), impairment of vision occasionally results from the arsphenamines (p 218), tryparsamide has no spirocheticidal properties (p 223).

Much space is devoted to the author's modification of the flocculation test for syphilis and to a defense of the contention that if the Hinton test of the blood is negative the cerebrospinal fluid will also be negative and examination of the cerebrospinal fluid is therefore unnecessary. This wishful thinking has been repeatedly disproved by others. No recognized syphilologic expert will agree with the author's light dismissal of the value of spinal fluid examinations in all types of syphilis. The literature is inadequately covered, only a few bibliographic references are provided, and none of the more revolutionary statements are adequately documented. There are no illustrations, but an adequate index is furnished. The book cannot be recommended.

The Story of The Middlesex Hospital Medical School. By H. Campbell Thomson, M.D. F.R.C.P. Consulting Physician to the Department for Nervous Diseases, The Middlesex Hospital. Written at the Request of the Council of the Medical School on the Occasion of the Centenary. Cloth. Price 10/6. Pp 182 with 52 illustrations. London: John Murray 1935.

In at least three ways the narrative of Dr. Thomson will attract and hold the interest of the reader. Casual details and intimate quotations, like lightning flashes, reveal the customs and manners of the successive periods described. Student behavior and amusements, as well as faculty traditions and academic formalism, are sympathetically portrayed. The history of the origin and development of this school also reads like a roster of the great names in English medicine during the century of its growth. William Hunter was connected with the hospital in its earlier days. Sir Charles Bell was one of the founders of the medical school. William MacMichael, author of "The Gold Headed Cane," was a member of the staff, as was also Jonas Quain, later professor of anatomy at University College. Charles Gower, Bland Sutton, Burdon Sanderson, Lander Brunton and Alfred Pearce Gould are names known to every student of medicine. Again, the record of this institution constitutes an epitome of the history of medical education. Nearly all the problems connected with the rapid growth of the medical sciences and the need for almost continuous readjustment of teaching methods and school organization are illustrated in this story of struggle and achievement. At the outset the memorial from a committee of the staff petitioning the governors to authorize the establishment of a school recites in a manner that could not be improved on today the necessity for combining medical instruction and hospital practice to the infinite advantage of both. It is interesting to note that in 1843 there was appointed a 'surgeon dentist' to the hospital. In 1896 the hospital and medical school which for sixty years had existed separately side by side were amalgamated into a single corporation. This unification was shortly followed by an affiliation with the University of London. After prolonged discussion Middlesex rejected the proposal to transfer to the university all the teaching of preclinical sciences, a decision abundantly justified by

the subsequent development of the school. The entire story presents once again in high relief the predominantly clinical character of the London medical schools, which has been their glory and has aroused the emulation of the rest of the world.

Sex Education. By Maurice A. Bigelow, Professor of Biology, Teachers College, Columbia University. Second edition. Cloth. Price \$1. Pp. 307. New York: American Social Hygiene Association, 1936.

This series of lectures, delivered in 1915, has been brought down to date by revisions which have done more to spoil what was originally a valuable manuscript than they have served to render it serviceable for today. Granted, as the author claims, that most of the positions he took with respect to sex education in the days when his stand required a fine courage are still tenable, the book would have been more serviceable unrevised, with suitable annotations, than in its present form. There is no longer any question among open-minded persons as to "whether" with respect to sex education, the question today is "how?" In the later chapters the author arrives at a consideration of how sex education ought to be carried out and handles the topic admirably. The earlier chapters, in the light of present conditions, are tedious and repetitious, restating as they do the case in favor of sex education, a necessity twenty years ago, a redundancy today. The form of presentation, as so often happens when lectures are published in book form, is neither a readable manuscript for the casual reader nor yet a textbook adequate for classroom purposes. The most useful material in the book is the chapter on bibliographies. There is an adequate index. Considerations of economy in publication, including the generous waiving of royalties by the author and the overhead by the publisher, unfortunately dictated the choice of a type too small for comfortable reading.

Die Vitamine und ihre klinische Anwendung. Ein kurzer Leit-faden von Prof. Dr. W. Stepp, Direktor der I. Medizin. Universitätsklinik, München. Doz. Dr. J. Kühnau, Direktor des Städt. Forschungsinstituts für Bäderkunde und Stoffwechsel, Wiesbaden, und Dr. H. Schroeder, Ass. Arzt an der I. Medizin. Universitätsklinik, München. Paper. Price 6.50 marks. Pp. 130. Stuttgart: Ferdinand Enke, 1936.

This monograph affords an extraordinary amount of information in brief compass. While it is concerned mainly with recent scientific studies, it refers also to the clinical applications that have been proved or attempted with the vitamins. These dietary factors now comprise an imposing array of alphabetical letters. Among the fat-soluble vitamins the authors classify and discuss vitamins A, D, E and K, the last mentioned being the antihemorrhagic factor which recent work has indicated is required by the chicken. The growth factor of Coward and his co-workers is also included in the fat-soluble group. Under the heading of water-soluble vitamins there are discussed vitamins B₁, B₂, B₃, B₄, B₅, B₆, B₇, C, H, J, and the extrinsic factor of Castle. Thus it is apparent that the authors have presented a complete study of all the factors that have been classed as vitamins, not only those that are required by man but those which have been shown or are believed to be required for the nutrition of certain animals.

As far as human nutrition is concerned, there is considerable interest in the calculations which the authors present at the end of their monograph regarding the probable daily requirements of man. Thus they calculate that the minimal adult requirements for vitamin A would be provided by 1 mg. of carotene daily for vitamin B₁, from 0.25 to 0.50 mg. of crystalline B₁, for B₂, 1 mg. of crystalline lactoflavine, for vitamin C, from 20 to 50 mg. of crystalline ascorbic acid, for vitamin D an unknown amount for adults but about 0.002 mg. of a crystalline vitamin D for infants.

The authors also have calculated the value of a number of foods in terms of the average weights of the various vitamins which they contain. The amount of vitamins A, B, C, D and G provided by various diets used in the treatment of disease has also been attempted. It will be noted that this treatment represents quite an advance over the unitage method of stating vitamin requirements. However, it is questionable whether such a system is reasonably well advanced for general adoption at the present time or even desirable in all cases.

It is interesting to note that the monograph closes with a brief discussion of "Schrotschussbehandlung" or "shotgun vitamin therapy."

Les hydrocéphales algues et subalgues d'origine otique. Accident méningé otogène purement hypartensile. Par Robert Bourgeois. Paper. Price 32 francs. Pp. 178. Paris: Masson & Co., 1935.

Any contribution that is helpful in arriving at a better understanding and treatment of the often perplexing and dangerous neurologic complications of otitis is always welcomed. Bourgeois presents one of the less common of these namely, the pathologic increase of cerebrospinal fluid. The general plan of the book includes a discussion of the neuroanatomy, the physiology of the spinal fluid, the pathologic anatomy, the symptomatology, the diagnosis, the pathogenesis and the treatment. An attempt is made to differentiate three types of hydrocephalus, the diffuse, the ventricular and that of the posterior fossa. The chemical constitution of the fluid is usually that of diluted cerebrospinal fluid. This is one of the most important aids in differentiating the condition from abscess in which both albumin and cells are usually increased. The section on differential diagnosis is perhaps not as complete as one might wish. Treatment, depending on the location of the fluid, includes chiefly lumbar puncture, dural incision, ventricular puncture and, in all treatment of the ear. The author does not allow the reader to become lost but frequently sums up in a pithy manner the matter that has just been presented. More than sixty illustrative cases are cited in the course of the treatise. The bibliography is ample, drawn from many sources, both native and foreign and throughout the work the author evinces a polite consideration of the views of others.

Sex and the Love Impulse. An Outspoken Guide to Happy Marriage. By J. H. Burns, B.Sc., Principal, the Children's School, Birling Gap, Eastbourne, England. Paper. Price 50 cents. Pp. 61. New York: Emerson Books, Inc., 1936.

This pamphlet is described in its own subtitle, "an outspoken guide to happy marriage" but there is more to marriage than sex. Other aspects of marriage are not ignored but sex is heavily emphasized. Certainly it is outspoken, and it is a guide in the sense that it gives useful information correctly. Its brevity and simplicity commend it. The necessity for basing a happy marriage on proper bringing up of the child is stressed in this connection the author displays what might be regarded as an excessive confidence in rules going so far as to promulgate rules for the emotions which might be regarded as a new high in regimentation. Pamphlets of equal merit by American authors are available at lower prices.

La broncografía en el estudio de las afecciones del tórax. Por Raul Piaggio Blanco y Federico García Capurro. (Trabajo realizado en las dependencias del Ministerio de Salud Pública.) Prólogo del Profesor Arce. Paper. Pp. 397 with 168 illustrations. Montevideo: Imp. El siglo ilustrado, 1935.

This work is based on the study of 386 personal cases of thoracic disease, with a total of 434 studies by bronchography. The incidence of serious pathologic lesions is higher than ordinarily encountered in North American practice, for among these cases were nearly 20 per cent of pulmonary hydatid cysts. Fifteen per cent were cases of pulmonary suppuration. Only twelve cases out of the entire list were pronounced normal. Neoplasms, faults of development, bronchial stasis and other bronchial disturbances, bronchial dilatation, pulmonary tuberculosis, pulmonary syphilis (probable), pleural effusions, pneumothorax, subphrenic processes and postoperative conditions made up the bulk of the cases included in this study. The authors deplore the fact that so many physicians are content to limit their x-ray study of the chest to the shadows which normally utilize only the contrast between the normal opaque organs and the organs which are normally permeable to the x-rays. The employment of opaque devices, such as iodized oil, has opened an entirely new field of study. The first section of this book is dedicated to the technique of anatomy and physiology of normal bronchography and is followed by a second clinical part devoted to thoracic disorders abundantly illustrated and adequately described. Contrary to experience with many of these publications the quality of the paper is such as to bring out fairly satisfactorily most of the excellent illustrations. A wealth of interesting cases have been gathered together in this interesting book. Due credit has been given to the professors under whose direction the investigation has been carried out. Among them are many names distinguished in Uruguayan medicine particularly that of Dr. Pedro Barcia, professor of radiology in the Faculty of Medicine of Montevideo.

Richtlinien für Schwangerschaftsunterbrechung und Unfruchtbarmachung aus gesundheitlichen Gründen. Herausgegeben von der Reichsärztekammer. Bearbeitet von Dr. Hans Stadler. Cloth. Price 3.75 marks. Pp. 180 with 84 illustrations. Munich: J. F. Lehmanns Verlag, 1936.

This small monograph concerns itself with the indications for therapeutic abortion and sterilization. Edited by Dr. Hans Stadler, a government official, it presents the legal status of this problem in Germany today. The minister of health has established a special board to which cases for abortion and sterilization must be presented for approval. The many legal restrictions and laws are of no interest to physicians outside of Germany. The medical considerations for abortion and sterilization are discussed in a number of separate chapters by individual authors. Each chapter deals with a separate obstetric or medical complication. Some of these chapters are well written and cover the subject completely, others are brief outlines and are of little value. Thus, the chapter by Seitz on the toxemias of pregnancy, the chapter by Lydtin on pulmonary tuberculosis, and one by Fritz Lange on heart disease and pregnancy cover these subjects briefly but completely. In general, the indications and contraindications for abortion and sterilization are well accepted in this country. On the other hand, a long chapter by G. A. Weltz, on the value of roentgenographic observations as an aid in the decision for or against abortion and sterilization, covers a wide variety of unrelated medical conditions and is of little value. Many other conditions are covered too briefly to be of value to the reader. This monograph was written to familiarize German physicians with the present status of abortion and sterilization in Germany, and it has added little to medical knowledge.

Pathologie und Klinik in Einzeldarstellungen. Herausgegeben von L. Aschoff, H. Ellae, H. Eppinger, C. Sternberg und K. F. Wenckebach. Band VII. Der endemische Kretinismus. Von Prof. Dr. F. de Quervain. Vorsteher der Chirurgischen Universitätsklinik Bern und Prof. Dr. C. Wegelin, Direktor des Pathologisch-anatomischen Instituts der Universität Bern. Paper. Price 24 marks. Pp. 206 with 120 illustrations. Berlin & Vienna: Julius Springer, 1936.

Professor de Quervain is chief of the surgical clinic at the University of Bern, Switzerland, and received his early training under Professor Kocher. Prof. Carl Wegelin is director of the institute of pathologic anatomy of the University of Bern. Both de Quervain and Wegelin have been intensely interested in the goiter problem, situated as they are in Bern near the center of the endemic goiter belt of Switzerland, where unfortunately a large proportion of the population is affected by a "goiter noxia" which results in cretinism. This monograph summarizes their lifelong study of the problem and presents in an authoritative manner the various clinical types of cretinism, the pathologic anatomy and histology, the pathologic physiology, the pathogenesis and the accepted methods of prophylaxis and treatment.

Your Baby and Child. A Book for Mothers. By M. C. Overton, M.D., F.A.A.P. Cloth. Price \$2. Pp. 224 with 2 illustrations. Lubbock, Texas: Your Baby and Child Publishing Company, 1936.

This is intended primarily for the mother as a guide in the general care of her infant or child. It is in no sense a medical book but a lucid and concise exposition of developmental phenomena and common ailments. The author is simple and direct in his style. The text is free from the usual formality, and the reader almost feels that he is conversing with the author. The material is recent and is in general agreement with the best medical thought. It is recommended to the intelligent mother as a guide and common sense exposition on subjects that are important and commonplace in the care of her child.

An Activity Analysis of Nursing. By Ethel Johns, R.N., and Blanche Pfefferkorn, A.M., R.N. Director of Studies, National League of Nursing Education. Prepared under the auspices of the Committee on the Grading of Nursing Schools. Cloth. Price \$2. Pp. 214. New York: The Committee, 1934.

In the first chapter the question is raised "What should the professional nurse know and be able to do?" The answers to these questions define the scope and method of the remainder of the book. Eight statements called conclusions but which are virtually assumptions, present the opinion of the authors as to what the professional nurse should know and be able to do. The importance attached to the public health and educational aspects of nursing is manifested here and throughout the book. The activities of nurses, for example are

deduced from eight lists, one of which is a "combined" list, one a list of hospital bedside nursing activities, one a list based on private duty nursing in the home, and the other five deal with various phases of public health nursing. In this light the problem of curriculum making is discussed and proposals are made for the further study of the curriculum as a continuing project. The appendix furnishes a generous collection of source material.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Workmen's Compensation Acts. Jurisdiction of State Industrial Commission over Medical Fees.—In Oklahoma, said the Supreme Court of Oklahoma, the state industrial commission has no jurisdiction to make an award to a physician furnishing medical services under a written contract between such physician and the employer or insurance carrier. Where the medical services are rendered at the instance of the employee and are not contracted for by the employer or insurance carrier, and the person rendering such services seeks to hold the employer or insurance carrier liable therefor, the commission has exclusive jurisdiction to determine the existence, extent and amount of the liability. Where the medical services are rendered pursuant to an oral contract between the physician and the employer or insurance carrier, both the state industrial commission and the district courts of the state have jurisdiction to make an award or render judgment for the value thereof. The jurisdiction in such a case is concurrent. Regardless of whether the medical services were engaged by the employer, insurance carrier or the injured employee, the state industrial commission has no jurisdiction to make an award for such medical services unless a claim for compensation to be awarded the injured employee has been filed with the commission.—*Swift & Co v. Walden (Okla.)*, 55 P. (2d) 71.

Importation of Contraceptive Devices for Legitimate Use Not Illegal.—The claimant, a physician specializing in gynecology, imported a package of rubber pessaries for experimental purposes to determine their reliability and usefulness as contraceptives to cure or prevent disease. The United States sought a decree in the district court, S. D. New York, directing the forfeiture, confiscation and destruction of the pessaries on the ground that they had been imported in violation of section 305 of the tariff act of 1930 (19 U. S. C. A. section 1305), which provides

All persons are prohibited from importing into the United States from any foreign country any article whatever for the prevention of conception.

It was not disputed that the pessaries were imported for a lawful purpose but the United States contended that the law declares illegal the importation of any articles susceptible of being used for the prevention of conception without respect to their having a legitimate use and without regard to the intention of the importer that they are to be so used. But, said the court, such an argument was declared to be unsound in *Davis v. United States*, 62 F. (2d) 473, wherein the United States circuit court of appeals for the sixth district had under consideration the proper construction of sections 334 and 396, title 18, U. S. Code, Annotated, which declare it to be unlawful for any one knowingly to mail or to ship in interstate commerce any article designed, adapted or intended for preventing conception. The court in the *Davis* case held that these sections do not prohibit the transportation of contraceptives in interstate commerce unless they are intended for illegal use. With respect to the present case, said the court the language contained in section 305 of the tariff act, taken literally would seem to prevent the importation by physicians of any article for the prevention of conception even though the physician desired to use it or prescribe it for the purpose of saving a human life. The intention to prevent such a proper medical

use, concluded the court, "is not lightly to be ascribed to Congress," quoting from *Youngs Rubber Corporation, Inc. v. C. I. Lee & Co., Inc.*, 45 F. (2d) 103.

The physician in the present case having admittedly imported the pessaries for a lawful purpose, the court held that they did not come within the condemnation of the tariff act. A decree was therefore entered directing the return of the pessaries to the physician—*United States v. One Package*, 13 Fed. Supp. 334.

Crimes Arsenic Poisoning, Demonstration of Poison in Body Not Essential to Conviction of Homicide—Three boys became ill with nausea, vomiting, abdominal cramps and diarrhea a few hours after the ingestion of candy prepared and given to them by the defendant. A physician, although unable to diagnose their condition, prescribed a purgative and an emetic to each of them. A few days later their illness was diagnosed by another physician as metallic poisoning, probably arsenic. One of the boys died twelve days after eating the candy, and another developed "seriously drawn legs—a sort of paralysis." The defendant was convicted of first degree murder and appealed to the Supreme Court of Appeals of West Virginia.

At the trial an expert medical witness, who had made an examination and chemical analysis of the organs of the dead boy's body, testified to the effect that the stomach was covered inside with a white, sticky mucus, and was red and irritated, and that he found the lining of the stomach to be thick and inflamed. This condition, he said, was indicative of an irritating substance in the stomach and probably was caused by arsenic poisoning. He further testified that chemical analysis of the stomach, kidneys and intestines did not reveal arsenic but that, considering the time elapsed between the onset of illness and death, arsenic, if it caused the illness, might have been eliminated from the boy's system before death. The failure of the chemical analysis, said the Supreme Court of Appeals, to disclose arsenic in any of the deceased's internal organs was not conclusive that arsenic was not the cause of death. "It is obvious," said the court, "that when a person who has received poison internally lives a number of days thereafter, emetically and laxatively purged, and the kidneys functioning, the likelihood of finding traces of the poison in the system would be much less than if death had followed within a few hours." For its decision, the court relied on *Commonwealth v. Dans*, 211 Pa. 507, 60 A. 1070, in which the court, in discussing an expert's testimony that if vomiting occurs in a patient suffering from arsenic poisoning there will be little arsenic in the body after death, said:

In this he was supported by medical authorities. Arsenic is not a strongly cumulative poison. It is temporarily deposited in the liver and other organs of the body after absorption but it is rapidly eliminated from the system by the urine, bile and other secretions. Should the person survive for two or three weeks no trace of poison may be found after death in consequence of its total elimination during the interim. *Reese's Medical Jurisprudence & Toxicology* 443. And it is not incumbent on the commonwealth to prove that a quantity of poison sufficient to cause death was found in the body before a jury can be allowed to find that it was the cause of death if the evidence sufficiently establishes the fact that the poison alleged to have caused death did kill the deceased.

Accordingly, the court concluded that the evidence justified the conviction of homicide by arsenic poisoning and affirmed the judgment of the lower court.—*State v. Koontz* (13 Va.), 183 S. E. 680.

Insanity Criminal Responsibility in Relation to Paranoia—The accused was charged with murder. He pleaded not guilty, and, under a provision of the California penal code, not guilty by reason of insanity. The jury found him guilty of murder and recommended imprisonment for life. A subsequent trial on the issue of the accused's sanity at the time of the commission of the offense resulted in a verdict that he was then sane. A motion for a new trial on the issue of insanity was denied and judgment rendered on the jury's verdict. The accused thereupon appealed to the district court of appeal, third district.

We are, said the district court of appeal, impelled to hold that the verdict on the issue of insanity was not supported by the evidence. The accused called ten nonexpert witnesses who related incidents strongly indicating that the accused was insane at the time of the commission of the offense with which he was

charged. There was evidence of insanity in his family supporting the theory that he probably inherited insane tendencies. Three expert witnesses, two of whom were appointed by the court, positively asserted that the accused was insane at the time of the commission of the homicide, that his mental disorder, classified as paranoia, precluded him from distinguishing between right and wrong and from realizing that it was wrong to have killed his victim and to have attempted to kill another individual. There was no substantial evidence in the record to the contrary. The prosecution produced none to rebut that advanced on behalf of the accused. The prosecution rested solely on the presumption of law that all men are presumed to be sane. A mere disputable presumption, said the court, that all men are deemed to be sane until the contrary appears from competent proof is of slight value in support of the verdict of sanity in the present case. The evidence of insanity is so convincing that the presumption of sanity is scarcely worthy of consideration. The presumption of the sanity of the accused was completely and effectually dispelled by uncontradicted evidence to the contrary. The trial court erred, therefore, in not granting the motion for a new trial. Error was committed, too, when the trial court instructed the jury that on the issue of the accused's insanity it was not necessary that the verdict of the jury be unanimous, that the issue could be decided by a three-fourths vote. Insanity, said the appellate court, is merely a separate defense to the charge of a crime. It is necessary that the jury shall unanimously determine the merits of a defense of insanity like any other defense to an alleged crime before the accused may be found guilty of the offense. The case was therefore remanded for a new trial on the issue of insanity—*People v. Chamberlain* (Calif.), 55 P. (2d) 240.

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below

of T Waves Obtained M Rohnow L N Katz and A Bohning
Chicago—p 88

Thrombo-Angitis Obliterans and Tobacco—Maddock and his associates point out that, from clinical observations, physicians have known for many years that tobacco smoking is harmful to patients with thrombo angitis obliterans. A reason for the injurious effect was found when, by means of skin temperature changes, it was shown that tobacco smoking produced constriction of the vessels of the extremities, this process further decreasing the already impaired peripheral circulation. Summarizing their observations, the authors state that the smoking of two cigarettes by women resulted in a drop in the skin temperatures of their fingers and toes, and in an increase of their blood pressures and pulse rates similar to those observed in men. Cigarette smoking by Jewish males caused a greater drop in the skin temperatures of their fingers and toes than occurred in Gentile males. This fact may be of significance in accounting for the greater incidence of thrombo-angitis obliterans among Jews than among other elements of the population. No relationship was found between skin sensitivity to tobacco and its cardiovascular effect from smoking.

T Wave in Lead 4 in Children with Rheumatic Heart Disease—Robnow and his collaborators point out that the value of lead 4 in conditions other than coronary disease has received little attention. The preliminary report by Levy and Brunn stimulated them to investigate more systematically the appearance of lead 4 in rheumatic heart disease. The authors felt that, since many of the patients with this disease were children, it might be advisable to determine the appearance of lead 4 in normal children of various ages and to establish criteria for comparison with children having rheumatic heart disease. The authors summarize their observations as follows: 1 Upright biphasic or polyphasic T waves in lead 4 are common in normal children, especially in the younger age groups. 2 The contour of lead 4 in normal children may change considerably when curves are repeated a few months apart. 3 Children with active rheumatic heart disease show a higher percentage of upright T waves in lead 4 than do normal children of the same age. The T wave tends to become inverted when recovery from the acute stage sets in and tends to become more upright when the disease process becomes aggravated. However, exceptions to these correlations are not uncommon. 4 An analysis was made

of the factors that may be responsible for the differences in the T wave of lead 4 between children and adults as well as between normal children and children with rheumatic heart disease. 5 The electrical field at the surface of the body during the inscription of the T wave was examined in a variety of conditions, with the result that a new view concerning the causes and significance of the upright and inverted T waves in precordial leads was revealed. 6 As a result of the present study it is concluded that the practical value of lead 4 in children suffering from rheumatic heart disease is definitely limited. Single records in individual cases do not add valuable information, and serial curves supply data which may be suggestive and are only confirmatory to information obtained from the ordinary standard three leads.

Gastro-Intestinal Symptoms in Hypertension—Robinson points out that in a clinic in which a large number of gastro-intestinal patients are seen, one is impressed with the number who have hypertension. The question arises whether these digestive complaints are not in some way related to the hypertension and its concomitant cardiovascular or neurogenic phenomena, or whether they are purely accidental and unrelated. It is recognized that hypertension is associated with nervous instability, vasomotor disturbances, migraine colitis and hyperthyroidism. It is also recognized that some of these conditions may give rise to gastro-intestinal symptoms. The author presents a study of sixty consecutive hypertensive patients whose systolic blood pressure reached 160 mm of mercury, or the diastolic 95 mm. or in whom a hypertensive heart was found at necropsy. Fifty-one of these patients had digestive com-

plaints during life, the other nine had some alimentary tract lesion of importance which was discovered at operation or at necropsy. Summarizing his observations, he states that, in the sixty cases of hypertension in which there were also gastrointestinal complaints, peptic ulcer occurred twelve times, an incidence of 20 per cent. This high incidence suggests a possible relation, but the series is too small from which to draw any definite conclusion. Colitis also was frequent; it occurred nine times, an incidence of 15 per cent. Hypertension, hyperthyroidism and a lesion in the alimentary tract, such as colitis or ulcer, occurred together seven times. This strongly suggests that the concurrence of these three conditions is not accidental but that they are related and that some general disturbance of a circulatory or nervous nature is responsible for this triad. The author thinks that it is reasonable to conclude that the gastro-intestinal symptoms seen with hypertension are to a considerable extent conditioned by the cardiovascular, neurovegetative and other phenomena concomitant with the hypertension.

Treatment of Peptic Ulcer by Means of Injections—Flood and Mullins show that the relief of pain in peptic ulcer by means of daily injections of histidine monohydrochloride has been reported by numerous workers. The statement is made that the pain usually disappears after several injections while the patients remain ambulatory and eat a normal diet. In evaluating the benefits of this method of therapy, control observations with some inert substance, such as salt solution or distilled water, usually have not been made. Such control studies are of particular importance because of the psychic factors in ulcer and also because of the tendency to spontaneous remissions in the disease. It was the object of the present study to compare a series of patients treated with histidine injections with a control group injected with physiologic solution of sodium chloride. Eighteen ambulatory patients with active duodenal ulcer were used. The diagnosis was confirmed in all cases by roentgen examination. Ten of the patients had been treated in this clinic for previous attacks of ulcer and were considered to be "stubborn cases." All patients except one had been having daily epigastric pain immediately before the onset of injection treatment. None of the group had had a recent gross hemorrhage and none had pyloric obstruction as measured by the presence of a gastric residue six hours after a barium motor meal. Twelve patients in the group were given daily intragluteal injections of 5 cc of physiologic solution of sodium chloride. The other six patients received 5 cc of a 4 per cent solution of histidine monohydrochloride in a similar manner. The authors found that daily injection of saline solution for a period of about three weeks was attended by relief of pain in eight of twelve patients suffering from active duodenal ulcer. Daily injection of histidine monohydrochloride was followed by relief of pain in four of six patients with duodenal ulcer. The authors suggest that the successful results in this type of therapy in peptic ulcer are due to the psychotherapeutic value of the injections rather than to the nature of the solution used. Relief of pain in peptic ulcer by injection of salt solution emphasizes the importance of the psychic factor in the disease. The evaluation of any therapy for pain in peptic ulcer should be controlled by comparison with the effect of inert substances administered in the same way.

Selenium Toxicosis and Pellagra—Barondes states that selenium itself apparently exerts no poisonous action but that the alkali selenites and selenates are very poisonous. When animals have eaten plants poisoned by selenium they become crippled and die in great numbers, especially on being exposed to the bright light of the sun. The disease "blind staggers" and alkali disease found among live stock has definitely been traced to selenium. A marked resemblance will be noted on comparing the symptoms of selenium toxicosis in animals to the symptoms of pellagra in man. The most striking of these are that: 1. Both suffer severely from gastro-intestinal disturbances and nervous and mental disorders that often terminate in complete dementia. 2. On exposure to the bright light of the sun during the spring and summer months skin manifestations present themselves in the form of vesiculations and actinic dermatitis. The other symptoms present become more aggravated and it is at this time that the mortality is highest. 3. During the fall months the skin commences to desquamate,

and by wintertime atrophic and pigmented areas resembling vitiligo make their appearance. 4. Patients with pellagra complain often of a garlic or arsenic-like odor in the mouth and breath. A somewhat similar odor is noted on and about selenium poisoned animals. As there is a disturbed sulfur metabolism in both pellagra and selenium poisoning and as sulfur has an affinity for selenium and vice versa, the administration of sulfur and diet rich in sulfur-containing foods would appear to be the proper curative and preventive measures to be instituted for both these disorders. The author advises that chemical examinations and spectroscopic analyses be made of the foods and soils in pellagrous districts to determine the presence and concentration of any and all toxic substances, so that the proper study of toxic limits, tolerance limits, diagnostic symptoms and remedial measures may be undertaken thus safeguarding the public health within the areas affected.

Dissection of Mosquitoes—Barber and Rice describe a method of dissecting mosquitoes for examination for malaria parasites. The method is accurate, rapid and easy to learn. It may be employed without the use of a dissecting microscope and enables one to examine the glands and stomachs in the fresh condition. The essential feature of the method is that the glands are pressed out of the thorax by means of a small cover-glass, under which they remain for examination. There is also described a method of making permanent preparations of glands, stomachs and a great variety of objects. Fixation, washing, preserving, staining, dehydration and final mounting are done without removing the cover-glass from the position in which it is found in the course of routine work. Excellent preparations can be made with a minimum of time and trouble.

Dustless Method of Spreading Paris Green in Malaria Control—Barber and his collaborators describe a method of spreading paris green without the use of dust. The essential feature of the method is the use of a mixture of paris green and kerosene, the latter not serving as a larvicide alone but as a vehicle for spreading the paris green and keeping it afloat. The mixture may be diluted with water and spread by means of a horticulturists' sprayer or placed undiluted on pebbles or other convenient projectiles and thrown widely over the breeding place. The choice of method of spreading the mixture will depend on the character of the breeding place and on other conditions.

Lesions of Cardiac Valve Rings in Rheumatic Fever

Gross and Friedberg describe the incidence and the gross and microscopic appearances of lesions in the valve rings and inter-valvular fibrosa occurring in ninety-seven cases of rheumatic fever. They divide the cases into six clinical groups which represent various courses taken by the disease. They show that each group presents certain general gross and microscopic features that bear a relation to the clinical grouping. Definite gross abnormalities were present in the rings of one or more valves of the heart in the first five groups. In the sixth group there occasionally appeared to be normal rings on gross examination. In general, the presence and severity of gross ring abnormalities corresponded to the extent of involvement of the remainder of the valve—the mitral, aortic, tricuspid and pulmonary being affected in that order. In the majority of instances all four valve rings showed definite abnormalities. The authors take up the microscopic appearance of rheumatic valve rings in each of the six groups and there consider the mechanisms that may lead to the involvement of the valve rings. They present new macroscopic and microscopic data on the development of the rheumatic lesions in the valve rings and discuss their significance with regard to the spread of the rheumatic infection to and from these sites. They show that their own observations, as well as those previously reported, are of value in elucidating the pathogenesis of other cardiac lesions. As the valve ring constitutes the proximal portion of the valve leaflet, the ring lesions are of considerable significance in studying the

development of rheumatic valvulitis. A description is given also of the changes that take place in nonrheumatic valve rings during the first eight decades of life.

Tuberculosis Among Primary School Children.—Boyd undertook the study in the first place to determine the feasibility of examining whole families, in an effort to explain the occurrence of tuberculous infection and demonstrable tuberculous lesions in a group of 1,143 children entering primary schools. He also attempted to determine the sources of tuberculous infection in children entering primary schools. In tracing the sources of infection it is obviously impossible to deal with casual contacts. These children have not been at school a sufficient length of time to have the number infected appreciably changed by contact with other pupils and with teachers. The incidence of positive tuberculin reactions in the 1,143 children was found to be 19.86 per cent. For 1,001 children aged 6 years the incidence of positive reactors was 20.08 per cent, for girls 20.70 per cent and for boys 19.49 per cent. The majority of positive reactors were not sensitive to 0.1 cc of 1:1,000 dilution of old tuberculin. The incidence of infection increased with increasing density of population. Demonstrable tuberculous lesions were found in the roentgenograms of 13.22 per cent of positive reactors, which was equivalent to 2.49 per cent of the whole group. Of fifty-one children sensitive to 0.1 cc of 1:1,000 dilution of tuberculin, twenty had positive roentgenograms. The incidence of tuberculous lesions demonstrable roentgenologically was seven times as great for those with 3 plus reactions as for those with 1 plus reactions. Of seventy-two families investigated, a source of infection was found in twenty-one. Of twenty-one patients with the disease in the primary form nineteen were adults and two were children aged 15 years with the adolescent type of disease. Seven new primary cases were diagnosed among 111 adults while one new primary case was diagnosed among 141 children. All the newly discovered primary cases were minimal, six being active and two apparently healed. Search for a primary case in the families in which young children react to tuberculin is a feasible method of tuberculosis case finding. Further investigation in other centers may show this method to be of practical value to school and municipal health units.

Latent Sources of Contact in Tuberculosis.—Shurly and Brachman find that tuberculosis may be active for weeks and sometimes for several months before producing recognizable symptoms. Apparently healthy people unaware of having the disease may therefore act as tuberculosis carriers. From the adolescent age onward such carriers are not infrequently found wherever people congregate in large numbers. Tuberculosis is more likely to spread where people gather regularly, whether for work, education, recreation or food. Some people knowingly

having active disease become a latent source of contact in deliberately masking their symptoms by calling their condition "bronchitis," "bronchiectasis," "pulmonary abscess" and the like. The authors recommend that boarders or lodgers should not be accepted, particularly in homes where there are children, without a roentgenogram of the chest first being taken. Teachers and other school workers should be required to have a roentgenogram with or without a preceding tuberculin test. High school and college students should be required to go through tuberculin test x-ray screening before being accepted for athletic teams. Modern case finding methods should be required in all places at which people gather regularly. Rehousing is strongly recommended in every so-called slum area. More education is advisable among some foreign nativity groups along the lines of inducing them to take advantage of hospitalization. Physicians may well carry out a tuberculin x-ray case finding program among the general population, especially from the adolescent ages upward, and particularly in the poor sections of large cities where there is overcrowding. Approximately 1 per cent of this group will be found to have the adult type of tuberculosis.

Sodium Thiosulfate in Treatment of Scabies—Kulchar and Meininger direct attention to a recent report by Ravaut and Mahieu, in which those authors described the successful treatment of scabies by the precipitation of colloidal sulfur on the skin through the interaction of sodium thiosulfate and an acid. The treatment is carried out as follows: The patient is directed to take a soap and water bath. After he is thoroughly dry, a 40 per cent aqueous solution of sodium thiosulfate is applied over the entire body except the head and face, particular attention is paid to the areas between the fingers, to the flexural surfaces of the wrists, and to the breasts, abdomen, buttocks, thighs and external genitalia. Fifteen minutes later 4 per cent hydrochloric acid is applied in a similar way, and one hour later the applications are repeated in the same order. The procedure is repeated the next day, on the following day the patient again bathes and changes to fresh clothing. All bed linen, sleeping garments and clothing previously used are sterilized by boiling for five minutes. As the solutions are stable they may be made up in large quantities and dispensed as needed. Four ounces (120 cc.) of each solution is sufficient to carry out the treatment. The authors used sodium thiosulfate in treating fifty patients with scabetic infestations of all degrees of severity. As a control, fifty patients were treated with an ointment prepared in the manner described by Greenwood. They reach the conclusion that the precipitation of colloidal sulfur on the skin by the interaction of a 40 per cent aqueous solution of sodium thiosulfate and a 4 per cent solution of hydrochloric acid provides a simple effective and economical method of treating scabetic infestations.

Paratherapeutic Articular Disturbances—Genner says that the term paratherapeutic articular disturbances is used to designate morbid articular conditions that develop in connection

with antisyphilitic treatment either during or subsequent to a series of injections (as a rule arsphenamine and bismuth) involving two toxic factors. On the basis of his investigation the author concludes that the paratherapeutic articular disorders are in a great majority of cases due to the administration of bismuth compounds and only in exceptional cases to the administration of arsphenamine. This conclusion is derived from an analysis of seventy-nine cases in a total of 2,235 cases in which antisyphilitic treatment was given. Cases of arthralgia were not recorded until arsphenamine-mercury treatment was replaced by arsphenamine-bismuth treatment. The articular pain was aggravated by continuation of the bismuth treatment so that this form of therapy had to be discontinued in a fairly large number of cases. The pain subsided when the bismuth therapy was discontinued. In only 4 per cent of the cases of articular disturbance did the symptoms begin to appear during or after a series of treatments with arsphenamine, in 54 per cent it appeared during or after a series of treatments with arsphenamine and bismuth compounds and in 42 per cent during or after a series of treatments with bismuth compounds alone. The last mentioned evidence concerning the connection between the articular pain and the bismuth intoxication is further emphasized by the fact that the onset of arthralgia is predominantly intratherapeutic (75 per cent), appearing often within a short time (from one to a few days) after an injection of a bismuth compound, and it is accentuated by each subsequent injection of this substance. An analysis of the individual cases showed several instances in which articular pain first appeared during a course of combined treatment (arsphenamine and bismuth compounds) and subsided when the treatment was continued with arsphenamine alone, while it recurred when a bismuth compound was again given.

Cortical Encephalomalacia in Infancy—According to Levin, the cerebral palsies of childhood have been intensively studied clinically and have been divided into a number of fairly characteristic categories. Knowledge of the pathology of this group of common neurologic conditions has not kept pace with clinical studies. The few patients who have died during acute stages of the illness showed on postmortem examination conditions other than inflammation. The author reports a clinicopathologic study of the case of an infant with convulsive attacks and hemiplegia. At necropsy, multiple areas of encephalomalacia were seen, limited to the cerebral cortex. Definite arterial lesions were present but they were not sufficiently severe to be alone responsible for the parenchymatous lesions. The condition was similar in many respects to that in other cases recently described and the author thinks that it represents a not uncommon pathologic basis for infantile cerebral paralysis. The case concerns an infant with convulsive seizures beginning at the age of 4 months and hemiplegia beginning at the age of 9 months. Death occurred in the ninth month from circulatory and respiratory collapse after trephining of the skull. On pathologic examination of the brain, multiple laminar softening were noted throughout the cerebral cortex, most marked in the parietal region of each side. The pial arteries showed calcification of the media intimal proliferation was present in the vessels and in the large basal arteries. In the areas of softening

there were a marked proliferation of the capillaries and an abundance of phagocytic cells containing fat. About the vessels were accumulations of cells, from which gradations could be traced to the fat-laden macrophages. The condition appears to represent an early stage in the development of diffuse or lobar cerebral sclerosis, a common lesion in infantile cerebral paralysis. The lesions appear to be due to alterations in the circulation of the cerebral cortex. Actual vascular occlusion is rarely found, and it is believed that vasomotor disturbances may play an important part in the pathogenesis of this disease.

Insulin Hypoglycemia in Epilepsy—Ziskind and Bolton point out that reports of many studies have appeared in the literature suggesting that epileptic attacks may be due to hypoglycemia. On the whole, the evidence has been indirect and not conclusive. The injection of insulin is known to induce convulsions in several species of animals. In fact, insulin was formerly assayed in rabbits by this method. Convulsions resulting from an overdose of insulin are of infrequent occurrence in adult human beings. Still, if hypoglycemia bears any etiologic relation to the seizures of epilepsy, one would expect insulin to produce convulsions in these patients more readily than in normal persons. Indeed, the direct induction of hypoglycemia in a group of epileptic patients might present the crucial evidence necessary to a solution of the problem. The authors report their investigations on this problem. They found that insulin administered subcutaneously in doses of from 10 to 60 units to forty epileptic patients was not accompanied by convulsions in a single instance. Superhydration produced by the intake of 7 quarts (liters) of water at the rate of 1 quart every thirty minutes in addition to injection of insulin was accompanied by four convulsions in the thirty epileptic patients tested. The convulsions did not coincide with the lowest blood sugar concentrations. Further, the same number of convulsions resulted in thirty-one epileptic patients in whom superhydration alone was produced. Spontaneous hypoglycemia is probably not a prevalent factor in the precipitation of seizures in epileptic patients. Convulsions occurred in one fourth of the patients receiving large quantities of water.

Relation Between Blue Scleras and Hyperparathyroidism—Rados and Rosenberg state that the clinical entity consisting of blue scleras, osteoporosis with spontaneous fractures and deafness and the dominant hereditary transmission of the syndrome have long been known to ophthalmologists and pediatricians. In recent years many authors have considered that alteration in the ductless glands may be the causative factor. Others have made an attempt to explain the syndrome as entirely caused by hypofunctioning of the parathyroid glands, involving hypocalcemia. In contradiction of this view, Dessoff pointed out the possibility that hyperparathyroidism might be the sole cause. The authors have made a detailed study of two cases and say that their metabolic study strongly confirms the decided differences in the pathologic osseous conditions existing in hyperparathyroidism and those associated with

blue scleras. In the usual cases of blue scleras associated with spontaneous fractures and hereditary deafness there are not sufficient variations in the values for calcium, phosphorus and phosphatase to warrant a supposition of involved endocrine disturbance. In osteogenesis imperfecta there is evidence of decided hereditary transmission, in contrast to hyperparathyroidism, which shows no such influence. Cystic fibrous osteitis is based on hyperactivity of the parathyroid glands, the usual cause being tumor formation within the glands, resulting in mobilization of the supply of calcium. The spontaneous fractures occur in adult life and are accompanied by a negative calcium balance, cyst formation and giant cell tumors of the bones. The small minority of cases in which blue scleras are associated with proved parathyroid disorder are rare exceptions, the pathologic features not constituting the usual picture. The most plausible explanation lies in the possibility that the condition of hyperparathyroidism has been superimposed on a preexistent congenital anomaly. Similarly, spontaneous fractures are clinical features of the other form of generalized osseous disease, osteogenesis imperfecta, associated with blue scleras and deafness. They occur in utero or in infancy or childhood, in contradistinction to the adult age incidence of hyperparathyroidism. The roentgenographic picture of the osseous condition is that of osteoporosis. There is absence of a negative calcium balance and lack of increased phosphatase activity in osteogenesis imperfecta, the latter being a distinguishing feature of the parathyroid syndrome. Furthermore, blue scleras are characterized by dominant hereditary transmission and are due to a congenital faulty differentiation or malformation of the mesenchyma.

Treatment of Diabetes Mellitus with Insoluble Insulin Compounds—Gray points out that in 1935 Bischoff and Maxwell reported that tannic acid was an effective precipitant of hormones of protein character and that the resulting salt was biologically more effective than the uncombined hormone. When commercial insulin was combined with tannic acid, a salt formed which was absorbed more slowly and had a more prolonged effect on the blood sugar of experimental animals than did the insulin alone. The effect was so striking that the question of its application to the treatment of diabetes in human patients immediately arose. Insulin tannate is a salt of insulin which is insoluble in the presence of sodium chloride at a pH acid to the iso electric point. It is prepared by mixing

in a hypodermic syringe equal volumes of U-100 strength insulin and a tannic acid solution. The resulting mixture contains 3 mg of tannic acid per hundred cubic centimeters. It has about 20 to 25 per cent more hypoglycemic action per unit than commercial insulin. Eighteen patients of various ages and with diabetes of varying degrees of severity have been treated with insulin tannate for periods varying from a few days to two weeks consecutively. Control of the diabetes has been possible when this compound is used alone or in combination with commercial insulin. Because of the relative insolubility of insulin tannate in human and animal tissues delayed absorption and hence prolonged liberation of free insulin occur. Increased effectiveness of insulin tannate over commercial insulin is shown by lower fasting blood sugar levels and smaller number of total units required per day when it is used. The hypoglycemic effect of insulin tannate has been compared to that of insulin protamine and found to be of about the same order. The cheapness and availability of insulin tannate recommend it.

Pregnancy and Hyperthyroidism—Bodansky and Duff found that pregnant rats possess a remarkable tolerance to thyroxine. Despite the administration subcutaneously, of 1 mg daily during the last ten to twelve days of gestation, such rats showed almost the same gain in weight as their untreated pregnant controls. However, a comparison of the weights before the thyroxine treatment was instituted and at the end of labor revealed a moderate loss in most cases, in contrast to the usual, absolute gain in weight of the control rats. The nonpregnant, thyroxine treated controls invariably lost weight. In a considerable proportion of the thyroxine treated rats the gestation period was normal. The number per litter was approximately the same, but the weight was somewhat less in the thyrotoxic group. A much greater incidence of stillbirths occurred in the thyroxine treated rats than in the normal controls. Although hyperthyroidism in the mothers produced a marked diminution of the creatine content of the myocardium and cardiac hypertrophy, no similar effects were produced on the fetal hearts, the size and creatine concentration being within normal limits.

*Antenatal Administration of Quinine. L. Smith. Atlanta—p 247

Antepartum Administration of Quinine—Smith resorted to antepartum administration of quinine salt in sixty normal pregnant women. He shows that quinine administered in small doses for three weeks before the expected onset of labor will increase the basic tone of the uterine muscle fibers and thus reinforce contractions. The increased tone of the muscles will hasten the development of the lower uterine segment and more positively develop the hydrostatic bag of waters, which will earlier efface the cervix and dilate the os. The general health of the patients is definitely improved by small doses of quinine, their appetite is improved and indigestion and heartburn, of which many complain in the late stages of pregnancy, are often entirely or greatly relieved. In the cases observed by the author, the first stage of labor took place painlessly and in many cases the first obstetric examination revealed an almost complete dilatation. In none of the cases did the obliteration of the cervix and dilatation of the os take as long as usual. Moreover the author as well as other observers noted a lower frequency of fever in the women who had been given quinine. There was no puerperal sepsis among the author's cases nor did he observe more than a normal flow of blood after delivery. He stresses that in no sense should this method of administering small doses of quinine be considered a method of inducing labor and he believes that it is now agreed by pharmacologists and

clinicians that quinine is not an oxytocic nor is it of any value in inducing labor. There was no apparent tendency of the patients to go into labor prematurely, and the estimated duration of confinement varied both ways just as the cases did in which no quinine had been given. The author did not have a case of precipitate labor, although several patients were delivered in a remarkably short time. There was no case of retained placenta in this series, and the number delivered by Credé's method was thirty-seven, whereas in a similar group he quinized the author delivered fifty-two by this method. Only normal cases were selected for the quinine treatment. There is probably a large field for this treatment in abnormal cases, but further experience is needed. When a long, slow labor is desired, so that the head may be molded or the passage be dilated more slowly, this treatment is contraindicated. The author used quinine dihydrochloride in doses of 1½ grains (0.1 Gm) three times a day beginning three weeks before the expected confinement, and he found only one patient who could not take the drug.

Effect of Avitaminosis A on the Prostate—In a study of the prostate in man, Moore and Mark observed five cases with metaplasia and inflammation, which resembled the effects of avitaminosis A. They investigated a series of rats on a deficient diet. Eight prepuberal and eight postpuberal white rats from the same colony were placed on a diet that was complete in all respects except for a deficiency of vitamin A. An additional four prepuberal and two postpuberal animals were fed the same diet and 2 drops of carotene in oil every three days. All animals were given 0.4 cc of wheat germ oil by mouth or hypodermically every ten days. There was an excess of food in the cages at all times. The prepuberal animals were 30 days of age and the postpuberal 100 days of age at the start of the experiment. Animals were killed or died after from eighty-five to 115 days on the diet. The control animals were killed after 115 days and showed no pathologic changes. All experimental animals at death showed clinical xerophthalmia. Vitamin A deficiency alone in the white rat was associated with atrophy of the testis and accessory sexual glands. This would appear to be indicative of some disturbance in the hypophyseal gonadal prostatic hormone relationships. Vitamin A deficiency in the rat was found to be associated with foci of inflammation and epithelial metaplasia in the prostatic acini and vesicular ducts entirely similar to that reported in other organs. Focal metaplasia and inflammation is occasionally encountered in the prostate of patients with extreme inanition associated with stenosis of the ureters. It seems probable that this lesion is due to vitamin A deficiency.

Effect of Mucin on Infections—Nungester and his associates point out that in 1932 they reported the observation that organisms suspended in gastric mucin and injected intraperitoneally into mice were more virulent than when inoculated in suspension in saline solution. The experimental work they report here deals with the effect of sterilized gastric mucin on the virulence of bacteria when injected into the host simultaneously with the organisms. They found that, when sterilized gastric mucin is used instead of saline solution as a menstruum for suspending various bacteria, the host is placed at a marked disadvantage and may succumb to what would otherwise be a sublethal infection. This effect has been noted when injections were made intraperitoneally, subcutaneously or intratracheally. The mechanism of the action is not yet understood. Mucin does not interfere with phagocytosis but does inhibit the bactericidal properties of phagocytic cells. It enables bacteria to survive in the body of the host for longer periods without diminution in numbers or it may allow the organisms to increase in numbers and so result in the death of the animal. The viscosity and cohesive properties of the mucin appear to be important indexes as to the effectiveness of mucin on bacterial infections. The authors think that their observations on the effect of mucin on the virulence of bacteria lie in two fields. First, it offers an additional method for studying infections in animals with organisms that normally do not infect the animal. Secondly, since mucin occurs in parts of the body that are prone to be the sites of infectious processes, as the respiratory tract the intestinal tract and parts of the genital tract one wonders whether or not the accumulation of excessive amounts of mucin in these sites under abnormal conditions might predispose such sites to infection.

Complement Fixation Reactions of Polysaccharide Extracts of *Brucella*—Higginbotham and Heathman prepared polysaccharides from seven smooth *Brucella* strains, including varieties *melitensis*, *abortus*, *suis* and *paramelitensis*. The results of the precipitin tests employing rabbit antiserum for each of the seven strains and solutions of the polysaccharides from the seven strains and the results of the precipitin tests employing patients' sera and the polysaccharides are recorded in tables. In every instance the polysaccharide extract from a given strain precipitated its homologous antiserum. The authors reach the conclusion that the results of the precipitin tests with the polysaccharide preparations from seven strains of *Brucella* seem to show that organisms otherwise classified as of the same type may possess variable antigenic properties. The precipitin test is not a satisfactory one for establishing the type identity of a *Brucella* organism, although extracts from three

of the seven strains were found to give a positive reaction only with the homologous type antiserum. The results support the contention that a polyvalent antigen including some local strains should be employed in the routine serologic examination for undulant fever. All the sera from cases of human brucellosis which showed agglutination with the stock antigens (*Brucella melitensis*, *abortus* and *suis*) gave positive precipitin reactions with one or more of the *brucella* polysaccharides. Although the series is small, the polysaccharide precipitin test would seem to have no advantage over the agglutination test as a routine procedure and has the disadvantage of being impracticable because of the time and cost involved in preparing extracts. The results of complement fixation tests with the *Brucella* polysaccharide extracts and specific antisera, as well as those with the extracts and patients' sera, were not as clear cut as the precipitin reactions.

Diabetes Mellitus in Pregnancy—Stewart points out that the danger of pregnancy in diabetes was extreme before the discovery of insulin. The outlook today is far less serious and with proper treatment with a weighed diet and the proper amount of insulin a great many pregnancies can be carried to term without the extreme danger that existed before the use of insulin. Even with this improvement, however the infant mortality rate according to certain authorities is 45.2 per cent. Consequently the situation is still very serious. The author thinks that, if the diabetic woman asks the physician whether it is safe to have a child, it is the physician's duty to tell the patient exactly what her chances are for herself and her baby. Diabetic patients are divided into three classes (1) those with mild diabetes, who can be controlled on a diet alone without insulin (2) those with moderately severe diabetes, who can be controlled on relatively moderate amounts of insulin (3) those with severe diabetes, who take large amounts of insulin and who show periodic diacetic acid and acetone. It is known that as soon as pregnancy exists the amount of insulin has to be increased. It is also known that if there is any vomiting there will be a degree of acidosis consequently the only safe rule to go by is to advise the patient with mild diabetes that the chances are fairly good but even today patients with moderately severe and severe diabetes should be advised against planning to have children. If the diabetic woman finds that she is pregnant, the internist should analyze her case carefully. The woman should be hospitalized and put on a basal diet plus about 15 per cent, and with a proper amount of insulin to see whether a normal fasting blood sugar can be obtained and also whether there is any diacetic acid and acetone in the urine, as well as to see the amount of carbon dioxide. The author thinks that, if there is a high fasting blood sugar with a carc-

fully weighed diet and fairly frequent suggestion of insulin shock when the insulin is given three times daily, also when diacetic acid and acetone are present and there is a somewhat diminished carbon dioxide, it is the internist's duty to refer the patient back to the obstetrician with the advice that a therapeutic abortion be performed to save the life of the patient. However, if there can be a good control of the blood sugar and there is very infrequent or no diacetic acid or acetone found in the urine after sufficient observation, the patient could go through a pregnancy and have a normal child. The author gives the history of a case which demonstrates what a serious problem pregnancy is in a woman with severe diabetes, the danger of anesthesia in severe diabetes and the increased severity of symptoms in diabetes complicated by infection of any kind.

Esophageal-Gastric Carcinoma Treated by Roentgen Rays—Baum reports the case of a man aged 53, first seen in March 1929. He complained of difficulty in swallowing and of substernal pain of about one year's duration. About a year previously, the patient had had a hemorrhage from the stomach vomiting a large amount of blood. Thereafter because he began to notice progressive difficulty in swallowing particularly solid foods he was on a fluid diet. The patient lost about 10 pounds (4.5 Kg.) in the last three months with considerable loss of strength. Roentgen examination of the gastrointestinal tract showed a marked dilatation of the lower end

of the esophagus, and distal to this a tumor mass involving the esophagus and cardiac portion of the stomach. A piece of tissue was removed for microscopic study, which revealed a squamous-cell carcinoma with hornification. High voltage roentgen therapy, the protracted fractional method, was immediately instituted following the establishment of a definite diagnosis of squamous-cell carcinoma. It was felt that a gastrostomy was not indicated, as the patient was able to take liquid nourishment and retain it. The technical factors were 200 kilovolts, 4 milliamperes, 70 cm. distance. Filtration was through 2 mm. of copper and 1 mm. of aluminum. Large portals averaged 400 square centimeters. Daily treatments were given. Cross firing of the lower part of the esophagus and cardiac end of the stomach was done through upper abdominal and right and left oblique portals, each portal receiving about 5,000 roentgens. Forty-two treatments were given over a period of sixty-nine days, the average dose per treatment being 480 roentgens. Each portal was given the maximum skin toleration dose until an epidermitis resulted. Early in the course of treatment, which was effective from the beginning, the patient began to show improvement in swallowing. Soon after the completion of the treatment the patient was able to take all solid foods. He had no substernal pain or pain when swallowing. The roentgenologic examination at that time showed only a slight degree of irregularity at the cardiac end of the esophagus, corresponding to the site of the original lesion. The patient has been seen and examined in the follow-up clinic for the last six years. When seen on March 29, 1936, his weight was 170 pounds (77 Kg.), a gain of 26 pounds (13 Kg.) since treatment. The author thinks that the success in the treatment may be due to limited localized involvement, the relative ray sensitivity of the growth, and the fractioning of the dose and prolongation of the treatment.

Effect of Roentgen Rays on Parenchyma of Thyroid.—Zimnitsky and his associates made experiments on the thyroids of twenty male rabbits, aged from 6 to 8 months. Fifteen were treated with roentgen rays, five being used as controls. The technic consisted of a Koch and Sterzel apparatus and the Coolidge tube, distance, 24 cm., filter, 3 mm. of aluminum, voltage, 140 kilovolts, 3 milliamperes, dose, 550 roentgens. The first lot of rabbits was irradiated three times, the second lot five times and the third lot ten times, the dose was given once a day. In order to study how time affected the development of the morphologic processes, rabbits were killed at twenty-four hours, six days, twelve days, twenty days or forty days after the treatment. For comparison, a control rabbit also was killed. The specimens of thyroid of both the treated and the control animals were fixed with Zenker's formaldehyde with the addition of acetic acid (Miloslavsky's method) and then were passed through a series of alcohol baths. They were then embedded in paraffin in the usual way. Sections of from five to six microns in thickness were stained with hematoxylin-eosin. The preparations made by this method served for a general survey of the gland conditions, but for fine cytologic examination the specimens were prepared by the Shampy method with a subsequent chromicizing, the paraffin section being from 2 to 3 microns in thickness. After removing the paraffin by treating the sections with hydrogen peroxide the authors stained them for chondrioma, using Kull's method. On the basis of their observations they reach the following conclusions: 1. The parenchyma of the thyroid has a considerable resistance to roentgen rays. 2. The fine cytologic preparation of a thyroid reveals more fully and more quickly the initial steps of the changes taking place in the cells under the action of roentgen rays. 3. Changes in the cells of a thyroid involve the protoplasm as well as the nucleus and chondrioma. In the cell protoplasm there appear vacuoles of various sizes. The chondrioma becomes coarse and granular and loses its regular distribution in the cell body, the nucleus of such a cell undergoes pyknosis, and some of the affected cells finally disintegrate. 4. The action of the roentgen rays on the organ follows the so-called island principle. 5. In addition to the foregoing changes taking place in the individual cells of the thyroid the chondrioma undergoes degenerative changes that is it becomes coarse and granular and loses its regular disposition in the cell body while the nucleus and the protoplasm

of the cell keep their morphologically normal structure. 6 Colloid in the follicles of the irradiated thyroid becomes granular, undergoes vacuolization and decreases in quantity in the organ. 7 The structure of the thyroid regenerates when a lapse of time is permitted after irradiation.

Cyclic Changes in Vaginal Mucosa.—In the histologic variations of the human vaginal mucosa, Traut and his associates found that there is a definite rhythm which it is possible to correlate with menstruation and hence with the ovarian cycle. This cellular response is characterized by proliferation on the part of the stratum germinativum, with increase in the number of young epithelial cells in the basophilic zone of the epithelium. This response is associated with occasional mitoses and definite leukocytosis and hyperemia. The proliferative phase appears in the premenstruum, lasts six or seven days and is either completed premenstrually or extends into the menstrual phase and occasionally into the postmenstruum. It has not been observed between the seventh and twenty-first days of the cycle. Between the proliferative phases the epithelium is quiescent. Such alternation between proliferative and inactive phases has not been demonstrable in pregnancy, which seems to indicate that the rhythm of the vagina is related to the ovarian cycle. Changes in the superficial and intra-epithelial layers of the vaginal mucosa could not be correlated with the menstrual cycle. According to the observations they are quite arrhythmic.

Prevention of Recurrent Renal Calculi.—Higgins believes that the recurrence of calculi can be minimized by adherence to a properly planned diet and the addition of vitamin A in cases in which surgery has been employed. He has followed this plan for four years. Determination of the chemical constituents of the calculus and the type of crystals and sediment present in the urine is of value. The exact hydrogen ion concentration of the urine from the kidney which harbored the calculus must be determined in order that a correct diet may be instituted. In cases in which the calculus is composed of calcium and magnesium phosphates, carbonate or oxalates, the high vitamin A acid ash diet is employed in a routine manner. Calculi composed of the calcium, magnesium phosphate and carbonate form in alkaline urine, and calcium oxalate may be precipitated in quite a wide range of urinary reactions. In these cases the acid-ash diet shifts the reaction of the urine strongly to the acid side. As a general rule an excess acid-ash of from 20 to 30 cc is necessary to maintain the hydrogen ion concentration of the urine at a point from 5 to 5.2. In some instances, additional oral medication is required to maintain this level. Ammonium chloride, 0.5 Gm. in enteric coated pills is

the most efficacious drug for this purpose and causes less gastro-intestinal symptoms than other acidifying agents. When a calculus is formed in alkaline urine and when the postoperative reaction is shifted to the acid side, check of the urine for uric acid and oxalate crystals or urates is necessary to prevent the recurrence of calculi. This can be accomplished by altering the diet so that the hydrogen ion concentration of the urine is changed to the point at which urates and uric acid and oxalate crystals do not appear in the urine. While in the hospital, the patient is taught to make his own hydrogen ion concentration determinations. These determinations are made half an hour before lunch to avoid the effects of the alkaline tide or of awakening respiration changes. The hydrogen ion determination reports are presented regularly to the family physician, who then can maintain the hydrogen ion concentration of the urine at the desired level by further adjustment of the diet or by altering the medication. In the author's experience, recurrent calculi are composed most frequently of calcium and magnesium phosphates (many also contain carbonates). Such calculi develop in an alkaline urine, and their recurrence can be minimized by the use of the high vitamin A acid ash diet, which shifts the reaction of the urine strongly to the acid side. Other therapeutic procedures which have been used in the past are employed also. While the patient is in the hospital, the dietitian instructs him daily concerning the diet, explaining why certain foods are allowed and others restricted. The mere listing and prescribing of acid or alkaline ash foods does not suffice—a careful, scientific approach is necessary to determine the percentage of acid or alkaline ash in the diet which is required to maintain the proper hydrogen ion concentration level in each individual case. The incidence of recurrent calculi can be reduced to a minimum by the close cooperation between the patient and the physician. Since the author has prescribed the use of a regulated diet high in vitamin A following the operative removal of renal calculi, in addition to the other therapeutic measures usually employed, he has reduced the incidence of recurrences from 164 to 47 per cent in his cases. In many cases, eradication of the infection has been observed after the patient has been on the high vitamin A acid or alkaline ash diet for a period of from two to three months.

Value of Vitamins A and D in Measles.—Mackay and her associates investigated the effect of giving vitamin D and vitamins D and A to children under 13 years of age with measles. The 697 cases were divided into three groups. The first group served as controls and had only the ordinary ward diet, the second group received in addition 3,000 international units of vitamin D daily and the third received the same amount of vitamin D with vitamin A in addition equivalent to 6 drachms (22.5 cc.) of cod liver oil. Comparison shows that on admission the children were fairly evenly divided between the three groups as regards age, incidence of pneumonia and incidence of otorrhea. They were also evenly distributed as regards the wards in which they were treated and the medical officers under whose charge they came. A comparison of fatality rates, incidence of pneumonia, otorrhea, all complications and skin lesions developed in the hospital, as well as a comparison of duration of pyrexia or length of stay in the hospital, affords no evidence of any favorable effect exerted on the course of the disease by giving either vitamin D or vitamins D and A combined. It is pointed out that this negative result may be due to the fact that the time of observation (average under twenty days) may have been too short to demonstrate any effect from vitamin therapy, and that the treatment may have been started too late, since in 81 per cent of the cases treatment was not started until after the appearance of the rash, say till the fourth day or later in the disease.

Multiple Primary Epithelioma in Lymphatic Leukemia.—Pulvertaft says that multiple primary carcinoma of the skin occurs in x-ray workers and in xeroderma pigmentosum and is particularly associated with those whose work is in the case

of sailors, leads to constant exposure to the elements. The case of a grave digger was unusual in that the cutaneous condition was in part carcinomatous and in part a complication of lymphatic leukemia. The author points out that lymphatic leukemia is usually considered a neoplastic disorder, and the association of two distinct malignant conditions, while of interest, is familiar enough. The chief point of note in this case is its bearing on the function of the lymphocyte in malignancy. Murphy, starting from the observation that there is consistently a lymphocytic infiltration at the growing edge of a malignant neoplasm, argued that the lymphocyte provided an important barrier to the spread of tumors. There is, however, evidence leading in the opposite direction. In cutaneous epithelioma invasion occurs only in tissues where lymphocytes are aggregated, and lymphatic glands are of all organs the most prone to secondary invasion. Leukemic deposits in the skin are of frequent occurrence and take many forms. The condition is fully described by Hirschfeld. In a long series of references no mention is made of the development of malignant changes in the superficial epithelium, and it has not been possible to find any instance of such a change. It seems probable, therefore, that the primary exciting factor for the epitheliomas was the long standing condition of xeroderma. In every case, however, the epitheliomas in fact developed in areas of leukemic infiltration, and this suggests that nutritional or other changes occasioned by their presence were the last straw for the already pathologic epithelium. It is remarkable that epithelioma consistently develops in areas affected by injuries of long standing where subepithelial fibrosis is a feature, this is found in lupus, old burns and scars and syphilis. There may be a purely nutritional basis for this fact, and the leukemic infiltration may have precipitated in this case a malignant change in which a defective blood supply to the epithelium was one factor.

Melanoma of Rectum.—Lindner and Wood describe a case which they regard as a typical illustration of melanoma of the rectum. Clinically the symptoms are similar to those of adenocarcinoma of the rectum, and the condition will usually be mistaken for that lesion. Blackish discharge on the examining finger, however, might arouse suspicion as to the nature of the tumor. If the speculum is introduced, the dark color of the growth will suggest its nature. In some cases there has been pigmentation of the anal orifice, and this appearance has sometimes been confused with thrombotic external hemorrhoids. The tumor in the present case was sessile, but in 33 per cent (Loques) of the recorded cases it has been pedunculated and may even present at the anus as a polyp. A melanoma bulges into the lumen of the bowel, it shows no tendency to spread in an annular fashion, causing stenosis, as is frequently the case in adenocarcinoma. If it obstructs the bowel it does so by a process of occlusion and not of stenosis. It resembles in this respect a sarcoma of the rectum. The almost uniformly low position and the exceeding rarity of melanoma in other parts of the alimentary canal suggest that it probably arises from the skin of the anal canal. Chaher and Bonnet believed that they were able to trace the exact point of departure of the tumor from the malpighian epithelium of the anal canal. The authors were not able to do this in their specimen but observed that the tumor tissue came into the closest relationship to the squamous epithelium of the lower part of the anal canal. The evidence afforded by a study of melanoma of the rectum seems to favor the origin of this tumor from skin. Regarding the spread of the tumor, they say that regional lymph nodes which contain pigmented cells are not necessarily the seat of metastasis.

Experimental Production of Peptic Ulcer in Ileum.—Wu and Thompson point out that peptic ulcer in the ileum is almost always associated with the presence of a Meckel's diverticulum which contains heterotopic gastric mucosa in its wall. The object of this study was to reproduce the lesion experimentally and determine some of the factors concerned. Seven dogs were used for this study. The importance of acid as a factor in the development of peptic ulcer has been demonstrated. On the other hand the presence of heterotopic gastric tissue in the ileum only occasionally leads to the development of peptic ulcer. While the difference in the outcome may depend on a qualitative or quantitative variation of the abnormal

gastric secretion or of the ileac contents, the theory of diathesis or individual susceptibility to the disease may also be invoked. That the alkaline ileac contents exert a protective or neutralizing influence against the acid gastric juice is shown by the development of peptic ulcer following the deviation of the intestinal current from the vicinity of the transposed stomach. The fact that ulcers are not invariably produced by such procedures calls for no explanation so long as there exists the possibility of regurgitation of intestinal contents into the side-tracked portion. Finally the development of ulceration in the ileum after the operation of surgical duodenal drainage to produce a jejunal ulcer had been added to the other two procedures is somewhat suggestive of a reflex nervous or hormone factor. Until secretory nerves to the islands of gastric tissue in a Meckel's diverticulum have been demonstrated, a hormone mechanism like that established by Ivy and Farrell in autogenous pouches of the fundic portion of the stomach transplanted subcutaneously in dogs appears to be more important from the clinical point of view. The observations made in this study seem to lend support to the hypothesis that the development of peptic ulcer in a Meckel's diverticulum containing heterotopic gastric mucosa depends on biologic, chemical and possibly reflex nervous or hormone factors.

*Smooth Muscle Tumors of Kidney. Report of Case and Review of Literature. J. F. Heggie and S. Alstead—p. 17

Smooth Muscle Tumors of Kidney—Heggie and Alstead say that, while small mesodermal tumors of the kidney are not uncommon, fibroma, lipoma, leiomyoma and so on, larger forms of these growths are relatively rare. Smooth muscle tumors of the kidney are of two kinds: small, often multiple, growths from 2 to 9 mm in diameter, not uncommonly found beneath the kidney capsule or in the superficial cortex—incidental post-mortem observations—and the rare large solitary growths of like character arising, possibly from displaced elements of the primitive myotome, in muscle fibers of the capsular tissues or of the walls of the renal pelvis or vessels of the cortex. As a rule the latter tumors are of slow growth and may be present for many years, the patient being aware merely of a swelling and a variable amount of discomfort or minor degrees of pain in the affected side. Dysuria and frequency of micturition are occasionally complained of. The authors relate the clinical history of a woman, aged 40, in whom roentgenoscopy disclosed a tumor above the colon and not attached to the bowel. On operation a large retroperitoneal tumor was seen on the right side of the abdomen. The upper pole of the right kidney was attached to the inferior aspect of the tumor, and the kidney as a whole was so much displaced in a downward direction that its lower pole was on a level with the brim of the true pelvis. There was no definite indication as to the nature of the neoplasm and it was not considered justifiable to incise it in case it turned out to be malignant. Accordingly the ureter was ligated and divided and the tumor with the attached kidney and suprarenal gland was removed. The patient made an uninterrupted recovery and is now quite well. The histologic examination of the specimen revealed no evidence of rapid growth or of malignancy. In discussing this case of simple fibrolipomyoma of the kidney the authors say that it might be argued that in this case the kidney need not have been sacrificed and that the tumor might well have been removed with the attached portion of the renal capsule. It should be remembered, however, that at operation the exact nature of the tumor and its origin could not be decided, and, as the tumor might well have been malignant, excision of tumor and kidney

was justifiable. It is probable that this tumor grew slowly from a small tumor of the variety "quite common, though always of minute size, beneath the capsule of the kidney," but its exact origin in this instance of advanced growth cannot be definitely stated.

Peripheral Nerve Injury Due to Pressure—Parker directs attention to three clinical criteria in the diagnosis of peripheral nerve injury due to pressure: (1) Both paralysis and anesthesia, collectively or separately, appear insidiously and may progress to complete nerve destruction; (2) the patient himself is the sole cause of the damage; and (3) he has no knowledge at the time or thereafter of the damage that he is doing. The first case illustrating this is one wherein the patient's own tissues provided the trauma. A woman aged 23, came for treatment because of weakness of her left hand. Twelve months before while milking cows, she had noticed a gradual loss of strength in extension of the fingers of her left hand, starting with the little finger and spreading gradually radiad to include by turn the middle and index fingers and thumb. There was atrophy of the extensor muscles of the fingers, and a corresponding groove could be found in the forearm. The extensor muscle of the thumb also was paralyzed. Palpation over the neck of the radius revealed a thickened nodular cord assumed to be the dorsal interosseus nerve. The diagnosis of paralysis of this nerve was made. The author points out that Learmonth and Woltman developed the hypothesis that compression of the nerve occurs between the aponeurosis of the common extensor and the supinator brevis. Accordingly they made an exploration and found that the nerve had made a groove for itself across the fibers of the supinator brevis. There is another clinical phenomenon wherein the abnormality of physical constriction is a likely cause of damage to a nerve. In this connection the author reports the case of a man with meralgia paraesthetica. This disorder is due to long continued compression of the lateral cutaneous nerve of the thigh. The author shows that the erect posture has a definite influence in causing meralgia paraesthetica but that there are other postural influences on nerves in connection with the lower extremities. As an example, there is the bilateral paralysis of the muscles supplied by the common peroneal nerve appearing in workers, such as beet planters and coal pickers, who are forced to assume a squatting position for hours on end. The obvious cause in this instance is compression of the nerve by the hardened and contracted hamstring muscles. Further, the author shows that the habit of crossing the knees may be a factor in damage to the peroneal nerve. Moreover, unilateral ulnar paralysis is not uncommon in patients convalescing from surgical operations.

Grafting of Endometrium and of Ovary—Solomons reports the case of a married woman, aged 28, who gave a history of ovaritis as a complication of mumps and a gynecologic operation in 1930 when an ovarian cyst with the ovary was removed. She was in a highly neurotic condition, had not menstruated for three years and had lost all feeling of sex. Examination at the time (August 1933) revealed a normal pelvis. She was admitted to the hospital, and numerous endocrine products were injected without the desired effect, i. e., to bring about menstruation. July 21, 1935, the abdomen was opened. A very small uterus was found. The ovary had apparently been removed on the left side, and the ovary on the right side was slightly cystic and adherent to the broad ligament. The uterus was then split and the endometrium exposed. It was very atrophic in appearance. A piece of endometrium was dissected from a uterus removed for multiple fibroids from a woman of 34 immediately prior to the operation and was grafted into the uterus of the patient by means of fine interrupted catgut sutures. In addition a piece of ovary which was attached to the removed uterus was placed in the right rectus muscle. September 25, two months after the operation, the first menstruation ensued, lasted three days and has been regular since.

Treatment of Staphylococic Skin Lesions with Toxoid—Whitby determined the amount of circulating antihemolysin in 100 normal persons in 200 cases of superficial lesions (carbuncles, boils, styes, sycosis and pustular acne) before and after treatment and in seventeen cases of deep-seated lesions (osteomyelitis). It would appear that the distribution of antihemolysin is the same in normal individuals as in those affected with superficial lesions. But the antibody is often definitely increased in deep-seated lesions—a useful diagnostic point in

obscure disorders of bone. The distribution of antihemolysin in normal individuals is approximately the same as that found by Parish, O'Meara and Clark. Titrations were carried out by the method described by these workers. In the 200 cases all the results followed on immunization with a total dose of 0.75 cc. of toxoid administered intramuscularly. The total dose was distributed in four doses of 0.05, 0.1, 0.2 and 0.4 cc. at intervals of one week. The 135 patients who recovered have been free from relapse for periods varying from two to fifteen months. All lesions were proved by culture to be staphylococic in origin. The most striking effects have been obtained with boils, styes and carbuncles. With regard to carbuncles, the majority have also been incised but are regarded as successes for toxoid in view of the speed of healing. In the small series of pustular acne and sycosis (seventeen cases) the toxoid did not appear to be more effective than vaccine. Only two patients with pustular acne recovered. Forman found toxoid of little or no use for the treatment of sycosis, but Connor has reported success in this disease after a long course of treatment. Thirty-seven patients exhibited temporary exacerbations during treatment. Of these, twenty-nine made rapid recovery within a few weeks of the fourth injection. Twenty-nine patients with boils recovered or improved with the dose adopted but subsequently relapsed after intervals varying from a few weeks to a few months. A second course has in most cases again procured relief, but to ensure complete freedom from infection most have had to attend for a monthly dose of 0.2 cc. of toxoid. Others have had subsequent successful treatment with a combination of toxoid and autogenous vaccine. Complete failure was experienced in twelve cases of boils. Seven of these patients were primarily bad subjects by reason of occupation or local skin disease, but five appeared to have a normal skin.

Administration of Physostigmine Derivative and Its Analogues in Myasthenia Gravis—Laurent and Walker have had eight patients with myasthenia gravis under care, who have taken dimethylcarbamate ester of hydroxy phenyl trimethyl ammonium methyl sulfitate, the physostigmine derivative, for more than a year. Working independently they have had the opportunity of using analogous drugs by injection and by mouth. The results which they have obtained by the latter method are particularly encouraging, and they believe that adequate relief will be experienced from oral therapy in many mild cases while fewer injections will be required in the more severe cases. Apart from drugs of this group, some of their patients have taken ephedrine and others have taken potassium chloride in large doses daily. Much larger doses of the drug are required if the oral method of therapy is employed. From 25 to 30 mg. gave a result comparable in intensity and in duration with the result seen after an injection of 0.5 mg. During the past few months the authors have received supplies of an analogous drug, methyl-phenylcarbamate ester of 3-oxyphenyl trimethyl-ammonium-methyl-sulfate. This drug has now been used by them orally in gradually increasing doses with success. They found that 10 mg. gave a demonstrable though weak result. The doses were gradually increased up to 90 mg., which gave rise to no pain or unpleasant side action. The oral method of treatment obviates the necessity for injections, gives a more prolonged action, and it would probably be possible by giving two or three doses to keep the patient at her best for the full twenty-four hours. The longer action should prove particularly useful in severe cases in which dyspnoeic attacks are liable to occur at night after the effect of an injection has worn off. Dimethylcarbamate ester of 8-oxy-methyl quolinium methyl-sulfate has an action nearly as intense as that of the first drug, but the duration is much shorter. Of the eight patients studied, five are somewhat better than a year ago and have suffered no relapses; two have had relapses from which they have recovered although the physostigmine derivative was continued throughout, and finally one patient died. The last had a very long history with previous attacks of dyspnoea before treatment began. She had two similar relapses after taking the physostigmine derivative and died in the latter of these while she was no longer under the influence of the drug. The treatment appears to have no direct effect on the ultimate course of the myasthenia but at the same time

it brings about improvement in the general health of the patients, as they are able to eat more adequate meals and to lead a more varied life

Uterine Bleeding and Estrogenic Substance—Zuckerman confirms by two experiments the fact that bleeding occurs during continuous theelin injections only when the amount given daily is a threshold or subthreshold dose. One monkey has never bled in the course of 220 days during which it has been given 1,000 international units of theelin daily, another, on 100 international units of theelin daily, bled between the forty eighth and fifty-second day of a course of injections which has thus far lasted eighty-nine days. In the light of these facts and in view of the accepted relationship between rat and international units, it is plain that a reasonable interpretation of Hisaw's two experiments is that his monkeys were being injected with threshold doses of theelin. It thus appears that the data which have been widely interpreted as showing that uterine bleeding is stimulated as a direct effect of the hormone during the course of theelin injections are insufficient to justify this conclusion. On the contrary most of the available facts are amenable to interpretation in terms of the established observation that uterine bleeding occurs only when the level of theelin falls below a threshold value. There can be little doubt that the present acceptance of the view that theelin during its administration normally and actively stimulates uterine bleeding is unjustifiable, and that, when it is used as a step in argument, it can only help to lead to hypotheses of the nature of the menstrual cycle (e. g., Robson and Henderson) that do not agree with the facts about the cycle derived from the experimental study of primates. The available evidence does not suggest that estrogenic substance actively stimulates uterine bleeding but still favors the view that bleeding is an event which marks the cessation of the hormone's action.

Surgical Aspects of Götter Problem. H R G Poate—p 842
*Ratio of Large to Small Lymphocytes in Persons Exposed to Lead Hazard D O Shiels—p 847
Cerebral Arteriography L C E Lindon—p 849

Treatment of Circulatory Failure—Wunderly says that it is convenient to divide the whole cardiovascular system into central and peripheral parts when considering the treatment of circulatory failure. Clinically, it is essential to know whether one is faced with a condition of central or heart failure or of peripheral failure. Central failure is usually accompanied by increased blood volume, peripheral failure by diminished blood volume. Following the classification of Wollheim, cardiac failure was divided into plus decompensation, which is characterized by dyspnea, orthopnea, cyanosis of the lips and the acral parts and increased venous pressure and minus decompensation, in which there is low blood volume, no dyspnea on lying down, patchy skin cyanosis and low venous pressure. The acute cases of minus decompensation correspond to circulatory failure in the severe infections. Minus decompensation is a peripheral circulatory failure, not a failure of the heart itself. In it four conditions are found: (a) decreased blood volume and insufficient venous return flow, (b) concentration of the blood, (c) decreased blood chlorides and (d) low venous pressure. The treatment of peripheral circulatory failure is the treatment of these four conditions. The most satisfactory method of increasing blood volume is by introducing fluids intravenously. These should be administered at the rate of 2 or 3 cc. per minute and large quantities are usually necessary. Blood is the best fluid. 6 per cent acacia solution is useful if the hemoglobin is not below 25 per cent and up to three or four liters a day should be given. The cause of the hyperpyrexial reaction is

discussed and methods of preparation of solutions and apparatus are mentioned. The drugs that are recommended to increase blood volume are strychnine, camphor, caffeine, epinephrine and solution of posterior pituitary.

Lymphocytes in Persons Exposed to Lead—Shiels points out that it has usually been accepted that the examination of white blood cells gives little information of value with respect to lead poisoning but that in a recent highly suggestive and interesting paper by Annie E. Ferguson and Thomas Ferguson it has been shown that the ratio of large mononuclear lymphoid cells to small lymphocytes has a closer relationship to the clinical condition than the stippled cell count, which has so far been regarded by most authorities on lead poisoning as of prime importance. Stippled cell counts depend to a considerable extent on the type of stain used, the technique of staining and the visual acuity of the observer, whereas the determination of the ratio of large to small lymphocytes is much less dependent on personal factors or on technique. The Fergusons pointed out that the precise differentiation between monocytes and large lymphocytes may be difficult, and they therefore included both types in the classification of large mononuclear lymphoid cells. The author did the same in the present investigation. He found that absorption of lead causes an increase in the ratio of large lymphocytes and monocytes to small lymphocytes. A fall in this ratio below 2:1 while the subject is exposed to the hazard is associated with definite symptoms of lead poisoning usually of sufficiently severe nature to cause incapacity. Generally speaking, the more severe the case, the lower the ratio. The magnitude of this ratio is more closely associated with the clinical condition than is the stippled cell count and it is a simple and useful indication by which to judge of the imminence or otherwise of lead poisoning and is an aid to diagnosis.

*Diagnosis of Cavities in Pulmonary Tuberculosis by Means of Tomograph J B McDougall—p 452
Congenital Heart Disease and Pulmonary Tuberculosis S R Gloyne—p 455

Diagnosis of Cavities in Pulmonary Tuberculosis by Means of Tomograph—McDougall asserts that tomography presents a further advance on all previous roentgen technic and that it is of special interest in defining cavities that may be obscured from direct vision in the usual anteroposterior films which form the great majority of all pictures taken in chest clinics. The tomograph can take actual sections of the chest at any level although for ordinary purposes three sections (ventral, dorsal and medial) are sufficient as a rule. The fact that the rib shadows are almost eliminated from the sections is of great importance, the sternum and the vertebral column are not shown as bony structures at all, although in dorsal sections the outer ends of the ribs and the outline of the vertebral column may appear. This unusual result is obtained by a simple but ingenious device that allows the tube and the film holder to move in contrary directions during the exposure, which is normally of one second. The secret of the success of the tomograph mechanism lies in the fact that the tube and film describe an arc of about 45 degrees during the exposure, this ensures that all objects in the plane of the chest which is being photographed are reproduced on the film, and that all objects lying outside this plane are projected away from the film. The arc can be lessened and in this way it is possible to obtain sections from some 3 mm thickness up to sections about 3 cm in thickness. If it is decided to take a picture through the entire thickness of the chest, the tube and film are kept stationary and one gets the usual anteroposterior picture without any elimination of the bony thorax. In a case of advanced tuberculosis with tubercle bacilli in the sputum the usual anteroposterior film shows a large cavity in the left upper lobe with two stout fibrous strands traversing the lower part of the cavity, but a ventral tomograph shows that the space in the left upper lobe is clear and that it ascends to the extreme apex. The medial tomograph shows what appears to be the origin of the fibrous bands seen in the anteroposterior film and there is still no evidence of a cavity wall in the left upper lobe. The space is, in fact, particularly

clear and gives the impression that it is not a pulmonary cavity but a localized pneumothorax, and that the dense shadow on the inner side is collapsed lung. On the right side of the medial picture, however, there is a veritable chain of cavities that are not in the anteroposterior picture. In the dorsal tomograph section the undoubted nature of the fibrous bands is made clear, for they are actually thick adhesions coming from the collapsed lung to the chest wall. On the right side of this section there is a large cavity with a dense upper wall.

Diabetes Insipidus and the Hypophysis in Children.—Without discussing in great detail the problem of diabetes insipidus and the hypophysis, Lereboullet and Bernard merely report several observations of diabetes insipidus in children and from these observations attempt to draw certain pathogenic clinical and therapeutic conclusions. In one case a typical diabetes insipidus developed during three years in a young boy without any accompanying sign of hypophyseal disorder being noted. The dechloridizing regimen and especially the administration of hypophyseal extract were effective, but only briefly, since it was necessary to repeat the injections four times daily. Even thus it was not always possible to suppress completely the abnormal polyuria. Hypophyseal medication subcutaneously seemed to be the only satisfactory method of treatment and was almost specific in its character. Observations of the disease in two other children gave similar results. They believe it possible to conclude therefore that diabetes insipidus in a child is most commonly apparent as a pure syndrome characterized especially by polyuria, polydipsia and some accessory cutaneous disorders and resulting in a loss of weight which can develop into a true cachexia. In the majority of cases objective signs of the hypophyseal lesion cannot be found. Complete integrity of the eyes of the sella turcica and of the cerebrospinal fluid is found repeatedly. It is indicated, nevertheless, according to the authors that the long continued administration of posterior hypophyseal extract to infants afflicted with diabetes insipidus carries with it the same therapeutic specific effectiveness that insulin does for diabetes mellitus.

- Critical Study of Experimental Cerebral Embolism Hermann and J. Dechaume—p. 455
Tuberculous Bacillema and Erythema Nodosum G. Graziosi—p. 473

Experimental Cerebral Embolism.—Hermann and Dechaume observed the effects of experimental carotid induced embolization and the resultant cerebral embolism on twenty-three dogs. The classic view that carotid embolization produces a cerebral embolization and a cerebral softening if the animal survives is well known. They succeeded in showing that in the cases in which embolization was rapidly fatal the embolism was encephalohulomedullary. The choroid plexus

and the hypophysis also were involved. Softening is not visible, but the lesions are complex and microscopic or macroscopic hemorrhages are especially conspicuous. The known physiologic and anatomic facts suggest the complexity of the experiment apparently as elementary as carotid embolization. Certainly the experimental embolism thus produced must be viewed with caution and be subject to revision. Such experiments demonstrate the possibility of producing paroxysmal hypertension by means of affecting directly the vasomotor centers in the cerebral-spinal axis, medullary centers, bulbular centers and, doubtless, other infundibulotuberian centers. The reality of such arterial hypertension by directly affecting the central nervous system is established. The pathogenesis of hypertension of cerebral origin observed in man in the course of cerebral vascular accidents may thus be revised. Finally the need for accurate physiologic and anatomic control of such experimentation is especially indicated by the results of such experimental methods.

Stenosis of Lower Third of Esophagus.—Guze reports sixteen cases of traumatic cicatricial stenosis of the lower third of the esophagus after the swallowing of a caustic liquid and three cases of inflammatory stenosis following old spasms. The classic treatment by gastrostomy has many disadvantages. The simple spasmodic contractures can be cured or at least improved by dilation with different sized bougies. In the inflammatory types of stenoses however, this treatment is unavailing. In such cases, circular electrolysis is of great help in allowing later dilation. In all those patients with gastrostomy observed by the author, it was possible by means of the treatment mentioned to close the gastrostomy wound and return to a normal method of feeding.

Serologic Changes in Patients with Liver Disease.—Freund calls attention to the fact that certain characteristics of human serum are closely related to the hepatic function. Continuing former studies, he decided to investigate two properties of human serum that are largely dependent on the function of the healthy liver: (1) the constancy of the complement content and (2) its trypanocidal action. He made tests on the complement content of the serum of patients with and without hepatic disorder and gained the impression that it is dependent on a partial function of the liver and that this partial function permits a conclusion about the condition of the hepatic parenchyma. The curves obtained by serial tests on patients during certain disorders permit a conclusion as to whether the hepatic parenchyma has been impaired or is in a stage of restitution. The serum of patients with hepatic disease frequently shows a considerable reduction in the trypanocidal power. It was found that the trypanocidal titer is closely related to the functional condition of the liver. 2. The trypanocidal substances or their preliminary forms are formed chiefly in the liver. 3. There is a parallelism between the complement titer and the trypanocidal titer. Thus it appears that the trypanocidal capacity of the human serum and its dependence on the liver represent also a partial function of the liver and one which is distinct from that manifested in the complement. In tests on 200 serums from patients with hepatic disorders and on a much larger number of controls the author was able to convince himself again and again that the trypanocidal action of the

serum is closely connected with a not yet identified partial function of the liver. He emphasizes that the described serologic functional tests are important for the prognosis particularly as regards the predisposition to infections. In tests on animals he found that those with impaired liver have a greater susceptibility to subsequent infections than have normal animals.

Adventitial Diffusion of Tuberculosis—Fenicia states that the lymph nodes of the hilus of the lung are the first structures involved in the process of chronic pulmonary tuberculosis. From the nodes the infection spreads to the parenchyma of the organ through the lymphatic vessels and the tunica adventitia of the pulmonary arteries and veins and of the bronchi. The tunica adventitia of these structures belongs to the reticulo endothelial system because of its structure, and to the lymphatic system because of its capillary and humoral circulations. The selective localization of chronic tuberculosis in the tunica adventitia of the pulmonary blood vessels with the consequent hyperplastic reaction results in the development of tuberculous hilitis in certain cases of which a reaction of sclerosis takes place and the sclerosed tissue marks the contours of the interstitial pulmonary tissue (tuberculous tramitis) or those of the pulmonary lobes (tuberculous perilobulitis). The anatomic and histologic study of the lung in these conditions show the special aspects of the organ. The roentgenogram shows a fine network of lines of increased density covering the field of the lung. The shadows of the network correspond to the early tuberculous infiltration of the spaces that limit the lobes of the lung. The roentgenographic anatomic and histopathologic aspects of the lung in tramitis and perilobulitis confirm the statement that pulmonary tuberculosis propagates itself from the hilus to the apex of the lung. Certain forms of chronic tuberculosis of the liver (the so called tied up cirrhosis of the French authors) and of chronic tuberculosis of the uterus evolve in a form similar to that followed by tuberculous perilobulitis. The anatomopathologic pictures of the structures in these conditions are analogous to those of the pulmonary process. These facts show that the tunica adventitia of the blood vessels of the liver and the uterus is the route of propagation of chronic tuberculosis in these organs and that a specific reaction of sclerosis takes place during the process, as is the case also in pulmonary perilobitis.

Van den Bergh Reaction in Cardiac Patients—Giordano made determinations of the bilirubin in the blood of patients suffering from decompensated heart disease by the van den Bergh reaction. He concludes that the quantity of bilirubin in the blood and the intensity of the reaction, whether direct or indirect, run parallel to the clinical evolution of the heart disease. Bilirubinemia and the intensity of the test increase with the aggravation and decrease with the improvement of the heart disease, especially in patients with decompensation of the right ventricle. The appearance of a direct reaction associated with increase of the bilirubin in the blood has an unfavorable prognostic significance for the patient's life.

- Influence of Roentgen Rays on Pregnancy Urine Evolution of Friedman Test Made with Irradiated Urine R. Bolaffi—p. 295

Effect of Irradiation on Substances in Urine of Pregnancy—Bolaffi's experiments were made on virgin rabbits previously laparotomized and placed in two lots for investigation of the effects of red and ultraviolet radiation on the bio-

logic activity of the gonadotropic and estrogenic substances contained in the urine of pregnant women. The author concludes that red radiations have no action on the gonadotropic substance, whereas they have a remarkable stimulating action on the estrogenic substance. Ultraviolet radiations have no action on the estrogenic substance, whereas they have an action on the gonadotropic substance by which the biologic activity of the latter is greatly diminished. The activation of the biologic action of the estrogenic substance by the red radiations and the weakening of the biologic action of the gonadotropic substance by the ultraviolet radiations are due to chemical and physical changes of the substances especially related to variations of their colloidal stability through photochemical and photobiologic effects of the radiations. The results of the author's experiments point to a subject of practical importance: the sensitivity of gonadotropic substance to ultraviolet radiations should be kept in mind with respect to the harmful influence that light may cause on the urine of pregnant women. When the latter must be used to make quantitative determinations for scientific or clinical diagnostic aims, it is advisable to use the urine as soon as possible after its elimination. If this is not possible the urine should be kept in a dark place to prevent alterations in the content or nature of the gonadotropic substance. The same precautions are advisable for the conservation of preparations for therapeutic purposes.

- Perforation of Gastroduodenal Ulcer M. Moya—p. 669
- Does Chlorosis Exist? G. Marañón—p. 677

Metabolism of Creatine in Muscular Dystrophy—Fernandez Cruz says that there is a disturbance of the metabolism of creatine in progressive muscular dystrophy which appears as a characteristic syndrome of pathologic creatinuria and a diminished elimination of creatinine. The administration of aminoacetic acid (glycocoll) to these patients for as long as it is necessary, produces a temporary increased creatinuria with consequent diminution of the elimination of the substance. Creatine, administered by mouth to these patients, is followed by elimination of the substance in proportion to the seriousness of the disease. The reaction shows that there is a creatinuric diabetes or intolerance to creatine in the condition. The administration of creatine by mouth can be used as a test for ascertaining both the degree of tolerance to creatine in patients suffering from muscular dystrophy and the condition of the muscular metabolism in patients suffering from myopathic pathologic conditions. In patients suffering from Addison's disease there is an abnormal elimination of creatine by the urine and a diminished elimination of creatinine. The latter is found in ninety-six out of ninety-seven determinations made. Creatine, administered to patients suffering from Addison's disease, causes an increase of creatinuria and slight changes of creatinuria. The results of the test point out that, in patients suffering from asthenia in Addison's disease, qualitative changes of the muscular metabolism develop that are different from those which take place in muscular dystrophy. The hypofunction of the hypophysis can produce a muscular syndrome associated with specific alterations of the metabolism of creatine that are characterized by pathologic creatinuria and intolerance to exogenous creatine. In patients suffering from muscular dystrophy injectable hepatic extracts increase the tolerance of the patients to creatine and decrease spontaneous creatinuria up to complete disappearance of the latter. Injectable adrenal extract administered to these patients does not produce modifications of creatinuria. In patients suffering from progressive muscular dystrophy the metabolism of carbohydrates is disturbed. Basal lactic acidemia is high and still higher after physical exercise. The content of phosphagen, glycogen and lactic acid in the dystrophic muscles, studied by biopsy, is greatly diminished. Histopathologic studies of the muscles in progressive muscular dystrophy show processes of destruction of the muscular tissues which are largely replaced by fatty tissue within inflammatory foci and areas of well preserved muscular tissues.

Voluntary Apnea in Chronic Respiratory Insufficiency—Castex and his collaborators made determinations of the time of voluntary apnea in patients suffering from chronic respiratory insufficiency due to cyanotic bronchopneumocardiac disease. Apnea, especially following deep inspiration, causes slight bradycardia. The arterial pressure slightly increases at the end of the test of voluntary apnea, following inspiration, whether or not preceded by physical exercise. Apnea during rest and with the patients placed in the dorsal position has an influence on the development of the P wave in the electrocardiogram. In apnea, following deep inspiration, the altitude of the P wave is greatly increased, whereas in that which follows expiration the wave rises only slightly above the iso-electric line. An intravenous injection of 1 mg. of atropine (paralyzing dose) makes less remarkable the differences in the development of the P wave in apnea following inspiration and expiration, respectively. The results demonstrate a predominance of the vagus nerve as cause of the variations of the P wave in apnea following expiration and a predominance of the sympathetic in apnea following inspiration. The great elevation of the P wave during inspiration in comparison with that which occurs during expiration indicates good condition of the auricle and can be taken as an index for estimation of the auricular function.

Monatsschrift für Kinderheilkunde, Berlin

- Congenital Diffuse Rhabdomyomatosis of Heart in Two Brothers. W. Pauli—p. 22
- Sino-Auricular Block in Child with Diphtheria P. von Koss—p. 30

Fat as Cause of Digestive Disturbances in Nurslings—Ružičić directs attention to the alimentary disorders caused by cow's milk. He conducted experiments to determine whether the fat as such or together with the other constituents of cow's milk causes the nutritional disturbances. A tabular report of the results of the experiments indicates (1) that nurslings tolerate an unusually large amount of cow's milk when its fat content has been replaced by the fat of mother's milk and (2) that the fat of cow's milk causes no disturbances when it is given in previously defatted mother's milk. The author says that, to the extent that observations on two cases permit conclusions to be made, it may be said that alimentary disturbances do not result from the fat of the cow's milk as such but only when it is given together with the other constituents of cow's milk.

Agglutination Titer in Dysentery—Martyn points out that the agglutination tests, which are employed for the serologic diagnosis of dysentery, have been highly evaluated by some but criticized by others. The agglutination can be influenced by a number of nonspecific factors. The author tested the blood serums of eighty nurslings and children who were free from dysentery for agglutination of the A, B, D and H strains of the Flexner Y group and of the Shiga dysentery bacillus. On the whole, he found in the different persons similar agglutination values. The H agglutinin usually had the highest values. In children in whom it could be proved clinically and bacteriologically that they had had dysentery, the agglutination values were qualitatively and quantitatively the same as in nondysenteric children from six to twelve months after the dysentery. Various irritations such as blood transfusion or the injection of certain substances may produce a considerable increase in the agglutinins, however, in these cases the clumping

is less compact and can readily be shaken apart. Moreover, this agglutination has no dysenteric character, there is no trace of a predominance of the agglutinins of the D and Shiga types. The agglutinins that appear under the influence of the aforementioned nonspecific irritants, as well as the increase of the agglutinins, are not identical with the processes that take place in specific agglutination.

- *Prevention and Raising of Premature Births H. Nevinny—p. 37
- Management of Birth in Narrow Pelvis Following Rejection of Cesarean Operation G. von Glinski—p. 66

Value of Tubal Insufflation in Sterility—Kleiner bases his evaluation of tubal insufflation on observations made in 146 cases. He stresses that tubal insufflation requires hospitalization, for its ambulatory employment or its use in general practice involves danger. He also rejects the therapeutic use of the method. A causal connection between conception and tubal insufflation can be asserted only if the following factors apply to the case under consideration: at least two years' existence of the sterility, conception not later than six months after the tubal insufflation, and exclusive use of insufflation without resort to other measures, such as curettage, the Alexander-Adams operation or laparotomy. The author thinks that the fact that after a positive insufflation conception takes place within the first six months in only 2 per cent of the cases but after negative insufflation in 14 per cent proves that tubal insufflation has no diagnostic value.

Prevention of Premature Births—Nevinny says that extensive antepartum care is of great importance in the prevention of premature births. By means of it the relative frequency of immature single births, with extremely low weight, can be considerably decreased. However, since even with extensive antepartum care there will occur a considerable percentage of premature births, it remains important to find the best methods of raising premature infants. In order to understand better the most suitable methods of care during the first period after birth, the author discusses the metabolism during this time, particularly the protein and sugar metabolism and the initial loss of weight. His studies brought proof for the great fluid requirements of premature births and he also observed that the fall and rise in the blood sugar curve runs parallel with the weight curve. In the treatment of premature infants he obtained good results with subcutaneous infusions of a slightly hypotonic solution of sodium chloride with the addition of a heart stimulant and of dextrose as a supply of energy. He illustrates the efficacy of this method by citing cases.

- *Influence of Defects of Cardiac Valves on Life Expectancy R. Friedmann—p. 382

Experimental Agastric Anemia and Pernicious Anemia—In his observations on hogs, Bence found that following total gastrectomy there develops during the first stage, which lasts for about a year, an anemia with microcytic, hypochromic blood picture, largely resembling that of chloranemia. Later, during the second or third year there develops a progressive, megalocytic, hyperchromic anemia which is combined with leukopenia, thrombopenia, icterus and urobilinogenuria. When the gastrectomized animals live long enough to enter the macrocytic stage, there develops in the medullary portion of the large tubular bones a severe red hyperplasia which entirely replaces the fat marrow. This hyperplasia shows embryonal character.

and correspondingly a severe, megalocytic erythropoiesis. The blood picture and the changes in the bone marrow are like those in pernicious anemia. In an animal in which at the age of 3 months 3 meters of the ileum and of the jejunum had been removed, the number of erythrocytes increased greatly as did also the hemoglobin, whereas the number of leukocytes remained unchanged. This experiment seems to indicate that the lower portion of the small intestine has no influence on the blood formation.

Copper Content of Blood in Anemias—In studies on the copper content of the blood of anemic patients, Bence and his associates found that it is increased, whenever the functional activity of the bone marrow is intensified, regardless of whether the existing disorder is pernicious anemia, secondary anemia, leukemia or polyglobulism. The causal factor of this increased erythropoiesis is unimportant. The increase in the copper values is not a peculiarity of pernicious anemia, for the values change during this disorder with the decrease and increase in the number of erythrocytes. The fluctuations in the copper content are closely related to the increased or reduced activity of the bone marrow. Immediately after a hemorrhage the copper content is low because during this stage of anemia the erythropoiesis of the bone marrow has not yet become completely established. A certain time is required until this mechanism becomes active. There are likewise high copper values in leukemia, during which an increased bone marrow function must be assumed. The copper values are increased whenever there is a numerical increase in the development of the erythropoiesis, and from this the authors conclude that copper or a substance containing copper is the chief factor in the numerical production of blood corpuscles. They assume the existence of two active principles in the erythropoiesis, in that copper directs the numerical production whereas the active principle of the stomach directs the activity of the bone marrow in the production of qualitatively normal erythrocytes.

Defects of Cardiac Valves and Life Expectancy—Friedmann compared the mortality rate of patients with heart disease with that of the population on the whole. The index of the latter was designated as 100. The excess mortality for all patients with lesions of the cardiac valves was plus 164 per cent, that of patients with mitral defects was plus 143 per cent. The highest excess mortality of the cardiac lesions was observed in patients with combined valvular defects in these it amounted to plus 226 per cent. In patients with aortic defects the excess mortality rate was plus 88 per cent, the lowest of all lesions of the cardiac valves. The mortality from all valvular lesions was greatest in both sexes during the fifth decade of life. However, in patients with mitral insufficiency it did not reach the peak until the sixth decade. The author investigated also whether the life expectancy of patients with cardiac defects was dependent more on the age of the patient or on the duration of the cardiac defect. He found that the peak of excess mortality during the fifth decade was largely independent of the time of acquisition of the cardiac defect. However, it was quite noticeable that the degree of enlargement of the heart was of considerable influence on the life expectancy of patients with valvular lesions.

Zeitschrift für Tuberkulose, Leipzig

- Serum Coagulation Reaction of Weltmann F. Fuente-Hita and E. Jubea—p. 255
- Influence of Age on Serum and Tissue Changes in Tuberculosis J. Zeyland and E. Piasecka Zeyland—p. 258

New Collapse Therapy in Pulmonary Tuberculosis—Werwath points out that artificial pneumoperitoneum was used at first only for diagnostic purposes but later was resorted to also in the treatment of severe cases of intestinal or peritoneal tuberculosis. He was induced to try it in pulmonary tuberculosis, because he observed that in pregnant women the increased abdominal pressure often improves the tuberculous processes of the lung. He reasoned that in cases in which

pneumothorax and phrenic exeresis failed to produce a complete collapse an additional compression of the diaphragm from below would help to produce it. He also hoped that the use of the pneumoperitoneum would reduce the number of cases in which extensive thoracoplastic interventions would be necessary and, on the other hand, might yet help some of the patients whose general condition is so unfavorable that a thoracoplastic operation would not be possible. In discussing the technic of artificial pneumoperitoneum, the author emphasizes that it is much less dangerous than an extensive thoracoplastic intervention. To be sure, particularly in the first filling, caution is advisable, in that not more than 500 or 600 cc of air is introduced into the abdomen. Depending on the condition of the heart, a preliminary treatment with cardiac stimulants might be advisable. When pneumoperitoneum is done the patient should be fasting and the intestine empty. It is advisable to introduce an intestinal tube about one hour before the intervention, so as to remove intestinal gases. An injection of morphine-atropine is given thirty minutes before. The local infiltration of the abdominal walls must be adequate so as to obviate reflex movements on the part of the patient and also to avoid unnecessary pain. The author introduces the needle in the hypogastric region, about the width of a hand below the umbilicus. The filling should begin while the patient is in the horizontal position. If it is well tolerated, the patient can gradually be brought into the sitting position. Should circulatory disturbances develop suddenly, the pelvis should be elevated at once. The first filling should be made on the operating table. The efficacy of the pneumoperitoneum is roentgenologically controlled during the next few days, and supplementary fillings of from 400 to 600 cc (up to 1,500 cc, depending on the size of the abdomen) are given at intervals of from two or three days to two weeks, until the collapse is complete. As a rule, the resorption of the air is more rapid in the abdominal than in the thoracic cavity. The favorable results, which the pneumoperitoneum produced in some rather desolate cases, prompted this early report, for the author realizes that the relatively small number of cases and the short period of observation do not as yet permit a definite evaluation.

Pneumoperitoneum in Pulmonary Tuberculosis—In this report Rehberg describes the histories of some of the patients in whom pneumoperitoneum was employed according to Werwath's method and discusses the various pulmonary processes in which this treatment is indicated. He employed it (1) in uncontrollable hemorrhages, whenever a pneumothorax or a greater collapse operation was impossible, and paralysis of the diaphragm alone was ineffective, (2) in tuberculous processes of the lower part of the lung, in which phrenic exeresis did not produce the desired effect, (3) in a number of cases in which pneumothorax had failed, and (4) in some cases of involvement of the upper part of the lung to intensify the effect of phrenic exeresis.

- Development of Reproductive Cells in Human Subjects G. Politzer—p. 1013
- *Cerebral Death in Chronic Pulmonary Tuberculosis in Light of Research on Serous Inflammation A. Sattler—p. 1015
- *Treatment of Genuine Epilepsy with Auricular Vaccine M. Tyndel and M. Pasternak—p. 1017
- Action of Autogonadotropic Hormone of Pineal Body on Rabbits P. Engel and W. Buño—p. 1018

Cerebral Death in Pulmonary Tuberculosis—Sattler states that in severe, chiefly exudative pulmonary tuberculosis with gelatinous and caseous pneumonia, he occasionally observed the sudden development of cerebral symptoms, characterized by disturbances of the consciousness, somnolence, psychic and motor unrest, pupillary symptoms, Babinski's phenomenon, pareses and so on. Stiffness of the neck and Kernig's phenomenon were usually absent. Headaches were rarely complained of. The patients usually died in less than six or seven days. The terminal stage was characterized by respiratory paralysis. Spinal puncture usually revealed increased pressure of the cerebrospinal fluid. Among six patients, whose clinical histories are described, there were two in whom the cultural examination of the spinal fluid revealed the presence of tubercle bacilli, whereas in the four others the results were negative. The necropsy revealed in all cases a cerebral edema but no

signs of a tuberculous meningitis. The author thinks that from the pathogenic point of view the cerebral edema represented a "serous inflammation" (in Eppinger's meaning of that term) of toxic origin. He suggests that the fact that tubercle bacilli are occasionally detected in the cerebrospinal fluid of such cases corroborates the true inflammatory character of the disorder, and he plans histologic studies (in analogy to Eppinger's studies on other organs) in order to find evidence for the vascular disturbance that is believed to be the pathogenic basis of such changes.

Treatment of Epilepsy with Antirabic Vaccine—Tyndel and Pasternak point out that attempts have been made in recent years to use antirabic vaccine in the treatment of certain diseases of the nervous system, such as dementia paralytica, tabes dorsalis and epilepsy. They decided to try it in patients with genuine epilepsy, selecting ten patients varying in age between 21 and 43 years. The vaccine is prepared by inoculating rabbits with an emulsion of fixed virus, killing them after seven days and then preparing an extract of their brains and spinal cords. The epileptic patients were given daily, for sixteen days, subcutaneous injections of 8 cc. of the vaccine. On the whole, the treatment was quite well tolerated, but it had no effect on the epilepsy. In view of the failure of the antirabic vaccine treatment in ten epileptic patients, the authors reject this mode of treatment.

Control of Grave Gastroduodenal Hemorrhages—In order to demonstrate the effectiveness of Witzel's method of ligation of arteries in continuity for the control of grave gastroduodenal hemorrhages, Kamenchuk performed ligations in forty-two cadavers and studied the effect in roentgenograms taken after filling the gastric and the duodenal vessels with contrast material. He found that in order to prevent the contrast material from entering the ligated segment it was necessary to make multiple ligations not only of the main arterial trunk but of its branches as well. This method, first proposed by Witzel, is indicated in life-threatening hemorrhages caused by ulcers of the lesser curvature which did not penetrate into the substance of the pancreas. The vessels to be ligated are the left and the right gastric arteries and their anterior and posterior branches. Ligation of the gastroduodenal, the right gastro-epiploic and the superior pancreaticoduodenal arteries is suggested for the control of hemorrhage caused by duodenal ulceration. In those cases in which the ligation of the pancreaticoduodenal artery is not possible because of dense adhesions between the duodenum and the pancreas, a duodenotomy with suture of the ulcer is preferable. Of twelve patients with grave hemorrhages treated by this method, four died. The cause of death was not due to persistent bleeding in three, while in one case it was the result of failure to ligate the gastroduodenal artery. The success of the method depends on the timely intervention and completeness of the operation.

Recurrence of Nephrolithiasis—According to Sokolov the so called kidney stone diathesis, resulting from a disturbance of the albumin or the water-salt metabolism, is responsible for the unpreventable recurrence of renal stones in a number of patients. Bilateral nephrolithiasis according to various authors occurs in from 14 to 15 per cent. In the author's material of 458 instances of stones in the kidney and the ureter there was an incidence of 8.58 per cent of bilateral occurrence. He estimates that about 25 per cent are not true recurrences but cases in which small stones or fragments of stone were overlooked during the operation. The operative intervention in itself with the consequent trauma to the kidney and the pelvis the stasis and infection of the urine, constitute favorable conditions for the new formation of stones. Disturbance of the calcium-phosphorus metabolism on the basis of

hyperparathyroidism has lately been considered a factor in the primary formation of kidney stones as well as in their recurrence. Among the important prophylactic measures the author stresses a delicate careful technic in the removal of stones excluding the possibility of overlooking bone spicules, careful roentgenologic revision of the kidney on the operating table, effective measures against urinary stasis and infection and the proper diet. Even more important is the study of individual factors in each case.

 Rhinolithiasis. A. Bergstrand—p. 475
 Additional Case of Choleic Acid Enterolith. J. Hellstrom—p. 480
 Thrombosis and Jaundice. Gosta Hultqvist—p. 483

Spastic Ileus—In Boman's patient, a man aged 23, with a wound infection in one foot but no gastric disorder and in good general condition, a disturbance with a picture of high ileus set in and resisted conservative treatment. On operation, the upper loop of the jejunum showed a sharp transition between a proximal dilated, reddened intestinal portion including duodenum and stomach, and a distal pale and collapsed portion. At the place of transition a round anemic edematous efflorescence appeared, followed by a contraction ring, which obstructed the lumen on palpation this disappeared, to be followed by another spasm in the same manner. The spasm is ascribed to a circulatory disturbance, and the circulatory disturbance in the intestine is regarded as a partial phenomenon of a general circulatory disorder expressed by the shocklike condition of the patient at the onset. This disturbance is attributed to intoxication from the wound with its breaking down products. A doubly fenestrated soft catheter was introduced in the stomach for drainage. Attempts to improve the circulation by administration of fluids and other means, and use of spasmolytics and other preparations to restore intestinal tonus through the vegetative system were without effect. On the sixteenth day the patient died in a new attack with collapse, falling temperature, pain and hiccups, together with marked aggravation of the general condition, small pulse and tachycardia. Necropsy failed to reveal any mechanical cause of the ileus or other positive results.

 Fatal Outcome of Pyelography? G. Ulland—p. 827
 *Gee-Herter's Disease. New Casuistic Contribution from Medical Division A of Rikshospital. O. K. Evensen—p. 830

Fatal Outcome of Pyelography?—In his report of a case of bilateral dilatation of the renal pelvis and the ureters due to cancer of the seminal vesicles with stricture of the ureteral orifices, in which urography with neo iopax was followed by uremic symptoms and which proved fatal on the fourth day Ulland stresses the need of caution in the use of urography in bilateral renal disturbances, especially if there are signs of insufficiency.

Gee-Herter's Disease—Evensen reports the case of a man aged 22 with a history of increasingly frequent periods of abundant porridge-like light stools since the age of 12 who was admitted to the medical division A of the Rikshospital for carpal spasm. His twin sister was treated for Gee-Herter's disease in the same division seven years earlier. The patient was mentally and physically somewhat infantile with a large abdomen reduced liver dullness rigidity and hypertony of musculature. Roentgen examination showed a large dilated colon open sutures in the cranium, deficient epiphyseal lines of the extremities and large and coarse spongiosa network everywhere. After the administration of 50 Gm. of dextrose, the blood sugar curve showed the characteristic low increase. Hypochromic anemia responded fairly well to treatment with iron. During treatment with calcium preparations and cod liver oil the blood calcium rose from 64 mg. per hundred cubic centimeters in April 1934, to 945 mg. per hundred cubic centimeters in August 1934. The blood phosphorus remained within normal limits. The patient's weight was increased 6 kg. and his height 1.5 cm.

ANTHRACOSILICOSIS

WALDEMAR C DREESSEN, MD

AND

R. R. JONES, MD

Passed Assistant Surgeons U S Public Health Service
WASHINGTON, D C

Most cases of silicosis are the result of inhaling dust that is not pure silica. An example is the disease caused by dust generated in the mining and processing of hard coal in Pennsylvania. The disease produced by this dust is termed anthracosilicosis and answers all the definition requirements of an occupational disease. Locally it is called "miners' asthma." It must, however, be differentiated from the pathologic state anthracosis common among most city dwellers.

Our remarks are based on a recent medical, engineering and statistical study¹ by the Public Health Service of (a) practically all the personnel of three representative mines, numbering 2,711, (b) 135 apparently tuberculous-free, disabled former anthracite workers who were studied intensively in hospitals, and (c) limited observations on the disease as observed in a tuberculosis sanatorium of Pennsylvania. It is our intention to outline briefly certain aspects of medical interest in anthracosilicosis.

Approximately 150,000² men were engaged in the anthracite industry of Pennsylvania in 1930, but various economic changes³ in the past fifteen years have caused a rather wide dissemination of anthracite workers throughout the country. Definite cases of this migration have come to our attention. Their significance as related to differential diagnosis in other sections of the United States is obvious.

ETIOLOGY

Etiologic factors pertaining to the pneumoconioses in general are well known to those practicing industrial medicine. We shall merely touch on certain dust factors of special importance in anthracosilicosis. Our studies showed that the hazard varied in different operations, according to the dust concentration and its free silica content. Therefore, in order to have a proper appreciation of the pathogenesis of this pneumoconiosis, it is necessary to know variations of this factor.

From the Office of Industrial Hygiene and Sanitation U S Public Health Service.

Owing to lack of space this article has been abbreviated for publication in THE JOURNAL. The complete article appears in the authors' reprints.

Read before the Section on Preventive and Industrial Medicine and Public Health at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

¹ Anthracosilicosis Among Hard Coal Miners. Bull. 221 U S P H S, Washington, D C, 1936.

² U S Bureau of Census.

³ Lubin, I. The Absorption of the Unemployed by American Industry. Washington, D C, Brookings Institute, July 1, 1929. Vol. 1 U S Census 1920 and 1930.

The median size of the dust particles that the anthracite worker is likely to inhale is about 0.91 micron, or about the size of a pathogenic micrococcus.

As regards the free silica content of the dust, the workers were arrayed chiefly into three groups:

1. Regular miners exposed to dust with a free silica content of from 3 to 4 per cent.

2. Workers in the haulage ways, exposed to dust with a free silica content of 13 per cent.

3. Rock tunnelers and muckers exposed to 35 per cent free silica.

These figures are characteristic exposures but are not all inclusive because they do not take care of mixed exposures and of a number of other factors. For example, the summary table of exposures (table 1) shows that about 43 per cent of the workers are employed as miners yet on statistical analysis some of these men had higher siliceous exposures than 4 per cent, thus bringing the proportion of miners exposed to a dust of low silica content down to 16 per cent.

Not all workers in a dusty trade are necessarily exposed to a dust hazard. For instance, 361 of the 2,711 active anthracite workers were exposed to less than 5,000,000 particles of dust per cubic foot of air and were used as controls in analysis of the data. As a concrete example of just how much dust the concentration of 5,000,000 represents, it has been found that municipal street cleaners are exposed to about this degree of dustiness. Nor has the Public Health Service in its various studies of workers in dusty trades⁴ found significant pulmonary fibrosis in any trade in which the exposure was less than 5,000,000 particles of dust (less than 10 microns) per cubic foot of air. Furthermore, the engineering phase of the anthracite study revealed that various methods of dealing with the dust problem have been introduced into the industry. As an example, the dry breaker (building in which anthracite coal is graded for market) is almost passe. The etiologic factors just touched on emphasize the importance of an occupational history.

For the individual case a typical example of the method used to determine the patient's dust exposure is shown in table 2. The last occupation listed is his present job. The weighted average dust exposure in each job is multiplied by the number of years in that occupation. The sum of all these products, divided by years in the industry, gives a fairly accurate estimate of the man's average exposure.

COMPOSITION OF ANTHRACOSILICOTIC LUNGS

Thirty years ago Wainwright and Nichols⁵ reported that, by analytic means then available, 33 per cent of the dried lungs of anthracite coal miners was foreign matter. In unexposed adults this percentage was only

1 to 3 King, McNally⁸ and Boehme⁹ report 0.14, 0.113 and 0.12 as the percentage of silica normally present in lungs. The total silica found in the lungs of anthracite workers in our study was between 1.20 and 1.86 per cent. These values approximate those found by others (table 3) examining lungs of workers who had been exposed to dust of hard coals.

‡ Dust count obtained from samples used for other occupations of similar exposure.

§ Average includes other samples.

It is interesting to note in this connection that the majority of compensation awards for silicosis among coal miners in Great Britain¹⁰ go to workers in the anthracite fields of South Wales. In Australia Badham and Taylor¹¹ report that it is the coal of low hydrocarbon content which produces the most fibrosis. Most important and of more than passing interest is the fact that in those regions of the world where the coal approaches the consistency of Pennsylvania anthracite

namely Wales¹² and Australia,¹¹ the advanced pulmonary fibrosis encountered on autopsy closely resembles that observed in the Pennsylvania anthracite miner.

PATHOLOGY

On gross appearance anthracosilicotic lungs are a dark gray, firm on palpation and usually heavy. In early cases a fine, black linear net work is noted on the surface of the lungs. The pleura is involved to a degree corresponding somewhat to the amount of parenchymatous involvement. Usually, fusing of the interlobar pleurae and scattered tough fibrous adhesions are noted between the visceral and the parietal pleura. Varying degrees of emphysema are noted. On section linear black markings and stellate, black fibrous nodules are noted throughout the lungs.

In more advanced cases considerable distortion in the lobes may be noted. There is more pleural involvement, and emphysematous blebs, often of large size, are present. The disseminated nodules tend to coalesce. The coalesced nodules on becoming confluent finally show up as large, black to gray areas of consolidation which replace large areas of functioning lung (fig 1) and tend to be predominantly subapical in location. These consolidations have been described by Cummins and Sladden¹² as cuirass-like sheaths and are usually as hard as a golf ball. The cut surfaces of these consolidated masses are blackened by the heavy impregnation of carbon (fig 2). Occasional strands and whorls of gray connective tissue may be seen in the cuirass. Not infrequently a central area of black, pasty, noncaseous necrosis, often with cavitation, is present. The lung tissue between the black masses in these advanced

carbonaceous material, frequently in cuirass-like masses in the infraclavicular regions of the lungs, a proportionate degree of pleural reaction, compensatory emphysema and chronic bronchitis or bronchiectasis.

Microscopically, black particles are present in the macrophages but they are rarely seen free in the alveolar epithelial cells. Collections of "dust cells" are seen, however, in the perivascular and peribronchial

Fig 1—Anthracosilicotic lungs of a miner aged 41 who had worked six years as a laborer at the face and fourteen years as a miner in a dry anthracite mine. Note the disseminated nodules identified by pigmentation and beginning to coalesce in the upper lobes of each lung.

lymphatics and adjacent interstitial tissue. Fibrous hyperplasia is observed quite early along the lymph channels and increases in certain areas to the formation of nodules. In the center of the smaller nodules, evidence of devascularization may be seen. The centers of larger nodules are for the most part well formed, white, fibrous connective tissue and commonly reveal evidence of hyaline degeneration but are often free of appreciable amounts of carbon. In the periphery of the nodules, dust-laden macrophages are present. Free extracellular dust is noted in large quantities in the adjacent underlying dense connective tissue (figs 4 and 5).

As confluence of the nodules occurs, the peripheral coal dust deposits are enclosed in the larger nodule formed. Areas of central, amorphous, finely granular necrosis are often seen. Fibrous hyperplasia and dense depositions of coal dust are seen in the peritracheal and pulmonary lymph glands, often to such an extent that histology of the organ is completely obscured.

ROENTGENOLOGY

In the scheme of x-ray interpretations shown in figure 6 the progressive changes might be regarded as portraying the pathogenesis of the disease. In this scheme we have drawn freely from existing classifications of silicosis. The influence of Pancoast and Pendergrass,¹⁴ Sampson¹ and the South African workers¹⁶ is quite apparent. Pancoast and Pendergrass¹⁴ in their studies of the pneumoconioses have

shown that a close correlation exists between the x-ray examinations and the underlying pathologic changes.

Individuals who have had little or no exposure will show changes indicated as the linear phase in figure 6, and a summation of the changes would be interpreted as "usual fibrosis."

The increasing linear shadows are indicated by commencing generalized fibrosis representing, pathologically, fibrosis and engorgement. Fibrous hyperplasia is beginning in tracheobronchial lymph nodes, along the lymph channels and in the adjacent interstitial tissue. A case showing this appearance in the x-ray examination is a borderline case. The important characteristic of the x-ray picture is that it is still linear. Should removal from the dust exposure be effected, recession in the prominence of the pulmonary markings might be expected (fig 7).

The next phase is exemplified by the x-ray film with a "ground glass appearance" and shown in figure 6 as the granular phase. Early in this phase a diminution in the prominence of the linear markings is noted, and later these markings are almost completely obliterated. It may be that pathologically the lymphatics are no longer engorged but are undergoing fibrosis with more and more dust finding its way into the interstitial tissue of the lungs and being retained.

About the time obliteration of the linear markings becomes definitely apparent in the granular phase, an early degree of nodulation will usually be present.

Fig 2—Anthracosilicotic left lung. Note large indurated fibrous mass blackened by carbon which has practically replaced all the functioning tissue of the whole upper lobe. Central portion of the mass shows necrotic necrosis and early cavitation. Note smaller firm mass in upper portion of the lower lobe and numerous scattered nodular and diffuse pigmented fibrous masses interspersed with emphysematous lung tissue throughout remainder of lung. Walls of bronchi and blood vessels thickened. Few scattered fibrous tags over pleura.

When nodulation becomes the predominant feature, the nodular phase has been reached. The nodules in this phase do not exceed 6 mm in diameter¹⁷ and

ANTHRACOSILICOSIS—DREESSEN AND JONES

JOUR. A. M. A.
OCT 10 19

measure for the most part from 3 to 4 mm. There is some variation in the size of nodules encountered in x-ray films of this group but in any one individual the nodules are fairly uniform in size unless infection is present. In this phase the hilar shadows are more dense than usual but not appreciably larger than those noted in the foregoing granular phase. In fact, in

tion of the costophrenic angles are frequently noted and in extreme cases lead to almost complete fixation of the diaphragm.

CLINICAL MANIFESTATIONS

The latent period of the disease, with the exception of rock workers, is approximately fifteen years, as less than 2 per cent of the workers developed the disease in this period of time.

It has already been stated that 2,711 active workers were examined. Of this number 616, or 22.7 per cent were diagnosed as having anthracosilicosis. Examination of almost all employees at the representative mine afforded us a sizable group of control individuals who were essentially of the same age, race and economic status. In the accompanying tables the examinations of the anthracosilicotic patients are compared with those of controls and a group of 135 disabled ex-workers who were later examined. The large group of active workers (2,095) essentially negative for anthracosilicosis showed changes of about the same order as the controls.

Symptoms—Apparently, the pathologic changes tend toward the production of rigid lungs. Clinically, therefore, the symptomatology is not unlike fibroid phthisis or, as Wainwright and Nichols⁶ stated, essentially a chronic bronchitis and emphysema. The cardinal symptom is dyspnea and is of a type that is singularly lacking in the orthopneic phenomenon. Like patients with fibroid tuberculosis, the individuals with well established anthracosilicosis are frequently

Fig 3—Anthracosilicotic right lung (same case as figure 2). Note massive fibrosis blackened by carbon in upper lobes and the extreme degree of emphysema in lower lobe. An area of moderately emphysematous lung tissue is present at the apex.

certain cases one gains the impression that the hilus is smaller. Where the hilar shadows are larger or a gross disparity in their sizes on the two sides is noted, infection is suggested. In this phase vicarious emphysema becomes quite readily discernible.

The next phase is the conglomerate. In this phase definite coalescence of the nodules has occurred. We have already noted how, pathologically this coalescence and confluence of nodules advance until all or the greater part of the upper lobes have been replaced by large masses of fibroid tissue containing entrapped coal dust. In such cases the basal portions of the lung show marked emphysematous changes often manifest to a degree as large blebs or bullae (fig 3).

An overlapping in the phases of pathogenesis has been shown because in the final interpretation of the film such features as fixation of the diaphragm, mediastinal distortion, childhood tuberculous lesions (Ghon's) early infraclavicular infiltrates and also certain clinical data must be considered. Some of this information, of course, is obtainable only by fluoroscopy.

The first signs of importance noted on fluoroscopy is a limitation (table 5) in diaphragmatic excursion due presumably to loss of elasticity in the lungs and not necessarily to pleural reaction. Later, concomitant with the changes occurring in the lung parenchyma the pleura shows proportionate involvement. Thus the diaphragmatic deformities such as peaking and obliteration

Fig 4—Section of anthracosilicotic lung. Note thickened pleura underlying collection of carbonaceous material, massive diffuse fibrosis with engulfed carbonaceous material and interlacing strands of nonpigmented white fibrous tissue. Reduced from a photomicrograph with a magnification of 16 diameters.

not sick enough to be bedridden nor are they well enough to engage in activities requiring more than slight exertion. Cough is a frequent symptom and is usually productive of black viscid sputum. The bronchial pathologic condition probably explains this symp-

tom. Chest pain is common and is usually manifest as a substernal sense of restriction or a pleuritic pain in the lateral bases. Not infrequently the pain is aggravated by the cough, and this occurrence is readily appreciated when diaphragmatic fixation, mediastinal distortion and pleural reactions are considered. Weakness is a comparatively late symptom. Among the

Fig 5—Small fibrous nodule showing entrapped coal dust. Reduced from a photomicrograph with a magnification of 80 diameters.

active workers it was offered as a complaint in 5 per cent of the early cases and in 14 per cent of the advanced cases. Hemoptysis may occur in the form of blood-streaked sputum as a result of an alveolar rup-

ture, but its occurrence at any time is suggestive of tuberculosis. Night sweats and loss of weight also suggest complicating infection.

The foregoing symptoms occurred at roughly twice the frequency among the complicated cases as in the cases not complicated by infection.

Signs—The clinical signs vary with the pathologic changes. About the time the anthracosilicotic patient is beginning to show a break in his respiratory compensation his general appearance is quite indicative of his physical status. There is a definite loss in the tonicity of the musculature of the upper arm, shoulder, neck

and chest with the exception of those muscles actively engaged in the accessory respiratory function. Loss of weight is quite marked, the skin is frequently of a dusky pallor and the face has a weather-beaten appearance. This general appearance has been referred to as asthenic or cachectic (table 5). It was observed in 30 per cent of those in an advanced stage of the disease, in 97 per cent of the disabled, but in only 4 per cent of the controls.

Dyspnea as objectively observed is even more reliable and frequent than as subjectively noted. In early cases it often required the functional exercise test¹⁸ to make it objectively discernible. The pulse and respiratory rate was taken at rest, immediately after and two minutes after the exercise. Obviously the response to this exercise is influenced by such factors as weight, age, cardiac condition, general physical condition and metabolism.

Another characteristic of the dyspnea is the prolongation of expiration. Its infrequency among controls indicates its importance in differential diagnosis. Because of the increased rigidity of the lungs and the accessory respiratory apparatus, the individual cannot empty his lungs rapidly enough to allow for great increase in respiratory rate. In the functional test the rate will usually be found elevated after the two minute rest period. Not infrequently this sign may be noted in well established cases merely by careful observation during the course of the medical examination.

Decreased chest expansion is a common sign, but a marked decrease is rarely encountered until the condition has progressed to a stage showing disability. The percussion note shows early bilateral impairment, later with consolidated and emphysematous areas in the lung it is respectively dull and hyperresonant. Fremitus is analogously altered. The breath sounds in early cases are bilaterally decreased, but with the formation of consolidations the breath sounds can be of

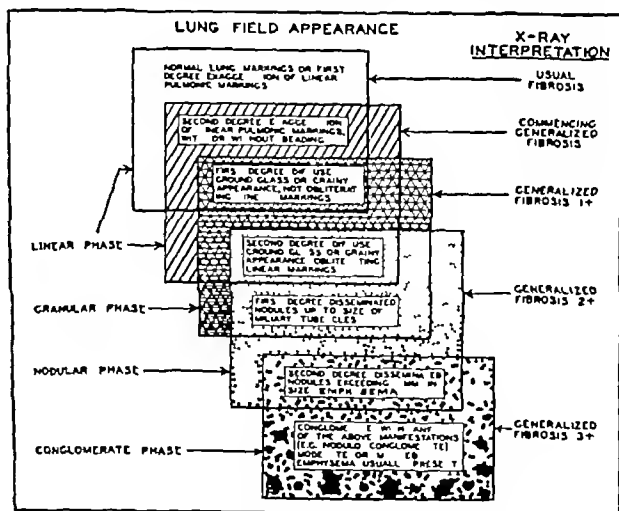

Fig 6—Scheme of x ray interpretations. Asymmetrical distribution of shadows, unilateral increase of markings and less discrete or coalescing shadows (mottling) imply complicating pulmonary infection and modify any of the phases illustrated.

almost any character depending on the location and type of the underlying pathologic condition. Râles and rhonchi are common adventitious sounds in anthra-

¹⁸ Except when contraindicated the test used was as follows: The individual places one foot on a chair or firm stand 18 inches in height and raises his body to the erect position twenty five times in thirty seconds.

cosilicosis Not infrequently they may be encountered in cases apparently not complicated by infection They are usually located in the interscapular areas or the lateral bases below the upper third of the chest

About one third of the affected individuals showed curved nails or early evidence of clubbing, which may be related to long standing fibrosis and bronchiectatic and emphysematous changes

Cardiac enlargement and other cardiovascular defects were not observed to the extent that might have been expected The higher prevalence in the disabled group suggests that it is a late complication

Fig 7—A miner aged 40 had been engaged in the following occupations: butcher's apprentice and butcher four years; lumber jack in the winter and laborer in paper mill in the summer four years; press mill operator in copper mill one year; outside laborer at anthracite mine one year; miner's laborer one year; contract miner eleven years. The estimated weighted average dust exposure was 192 million particles per cubic foot. There were no complaints. The respiratory rate remained elevated after the exercise test. Note the bilateral coarse granular appearance of the lung fields with beginning nodular shadows. The linear markings are almost obliterated.

On analysis this excess was found to be confined to those affected with anthracosilicosis because less than 1 per cent of the controls and about 2 per cent of all

those negative for anthracosilicosis (2095) had clinical tuberculosis. In the case of the affected workers, on the other hand, the percentage with clinical tuberculosis complicating the anthracosilicosis was 15 in the early cases and 43 in the advanced cases. A positive

history of tuberculosis contact did not explain the higher frequency among those with anthracosilicosis.

When both tuberculous and nontuberculous infections were considered, it was found that 23.9 per cent of all active workers were affected. Such infections complicated 58 per cent of the early cases and 92 per cent of the late cases of anthracosilicosis.

In the 135 disabled, apparently tuberculous free ex-workers so studied, all symptoms and signs were more universally present (table 4). Gastric distress was strikingly prominent in this group. About one third gave a history of hemoptysis. Only twelve (8.8 per cent) had fever, which ranged from 99.2 to 102.5 F. Night sweats were observed in only 8 per cent, yet thirteen (about 10 per cent) were shown to have positive sputums. These sputums contained acid-fast bacilli which produced lesions of tuberculosis when injected into guinea-pigs. Although hemoptysis was recorded in 30 per cent, only five of those with positive sputum gave a history of spitting blood.

In comparing the clinical course of tuberculosis in cases with pneumoconiosis and those without pneumoconiosis, it was learned that in the pneumoconiotic shortness of breath is always an initial symptom, whereas in tuberculosis uncomplicated by pathologic conditions caused by dust it is a late secondary symptom. The pneumoconiotic cases showed less tendency toward cavity formation. Cough, chest pain and weight loss occur later in pneumoconiotic patients.

Thus it would seem that the relatively low febrile reaction, the proliferative rather than the exudative type of tuberculosis, the marked dyspnea and the gastric distress point to chronicity. Moreover, these observations on tuberculous infection among the disabled ex-workers closely parallel those of Williams¹⁹ on old and retired Welsh coal miners.

DISABILITY

On the basis of all clinical data in each case, the active workers (2,711) were classified according to disability as follows: none, slight, moderate or marked. Irrespective of the degree, about 63 per cent with anthracosilicosis showed evidence of disability, as compared with 9.7 per cent of the control group. This excess of disability might be assumed as attributable to the direct or indirect effects of dust. If slight disability for which the worker is able to compensate is disregarded, it was found that moderate and marked degrees handicapped 20.9 per cent of those with anthracosilicosis and only 1.7 per cent of the controls.

Fig 8—A miner aged 52 had been a contract laborer seven years and a contract miner twenty-six years (fourteen years in gangway work and nineteen years at the breast). He had been a farmer before entering the mines. The estimated weighted average dust exposure was 123 million particles per cubic foot. Definite symptoms and signs were present. Note the symmetrical nodular shadows beginning to coalesce and emphysema.

SUMMARY

1 Anthracosilicosis (miners' asthma) is an occupational disease characterized by silicotic pulmonary

¹⁹ Williams, E. M. The Health of Old and Retired Coal Miners. South Wales Cardiff, Wales University of Wales Press, Portland, Me. J. 2: 389 (Aug. 26) 1933.

fibrosis, excessive retention of carbonaceous material and emphysema. Like other forms of silicosis, it renders the sufferer susceptible to tuberculosis late in life.

2 The chief subjective symptoms found in early cases of the disease are shortness of breath, cough and pain in the chest, later weakness, gastric distress and hemoptysis occur.

3 The most common objective symptoms observed are dyspnea, prolonged expiration, decreased expansion of the chest, curving or clubbing of the fingernails, changed breath sounds, altered fremitus and impaired resonance.

Fig 9—A miner, aged 55 had been a mine laborer in anthracite for three years and a contract miner for twenty three years and a company laborer for the past six years. The estimated weighted average dust exposure was 390 million particles per cubic foot. Symptoms and signs of well established anthracosilicosis were present. Note the conglomerate areas of fibrosis emphysema and diaphragmatic deformity.

anthracite mines, 616 (22.7 per cent) were found to be affected with anthracosilicosis.

5 The prevalence of clinical pulmonary tuberculosis in those with anthracosilicosis was 15 per cent in the early cases and 43 per cent in the late, well established cases. Among the controls and those essentially negative for anthracosilicosis, the prevalence was respectively 1 and 2 per cent, or about the same as in the general population.

In more advanced cases, or in cases complicated by infection, persistent râles and such constitutional impairments as loss of weight, cardiac defects and cyanosis are often noted.

4 In a study of 2,711 active anthracite workers, including practically all the personnel of three representative

dyspnea associated with silicosis which we have also found true of the dyspnea associated with anthracosilicosis. It is this. Individuals with dyspnea resulting from true asthma or circulatory disturbances are orthopneic. They must be propped up in bed to be made comfortable while the silicotic individual evidencing this symptom is not usually orthopneic—he is just as comfortable lying down as he is when sitting up. We hospitalized 135 patients with advanced anthracosilicosis, and this same peculiarity was shown by those with marked dyspnea. The only exceptions were those with cardiac complications.

Dr. R. R. SAYERS, Washington, D. C. Dr. Jones stated that it takes a long time for anthracosilicosis to develop. After fifteen years of exposure, only 2 per cent had the disease in the very early stage and without disability. But after twenty-five years and longer, 90 per cent of all exposed had the disease in some stage, some with disability. Exposure to underground conditions other than the exposure to dust did not predispose to respiratory diseases, as a matter of fact, men under these conditions had less respiratory disease than the general male population of the same age groups, while those exposed to dust and working underground had a much higher rate.

INTRAPROSTATIC INJECTION

AN EXPERIMENTAL STUDY

VINCENT J. O'CONOR, M.D.

AND

ROBERT L. LADD, M.D.

CHICAGO

In 1917 Cano, Townsend and Valentine¹ suggested direct medication of the infected prostate gland by perineal injection of a methyl phenol and a normal phenol serum. The method was not widely adopted.

Fig 1—Normal dog prostate. a urethra, b capsule, c normal glandular structure.

ABSTRACT OF DISCUSSION

MR. P. W. GUMAER, West Englewood, N. J. What are your lower limits and how does it compare with the smoky city atmosphere?

DR. R. R. SAYERS, Washington, D. C. I believe that the number of particles would vary. It would be very great in the city much more than the 360,000,000 particles per cubic foot as shown to the individual that he had on his table. Then the authors explained that 361 were used as controls. These were exposed to 5,000,000 particles or less. They also stated that this was about the equivalent of very dirty places found among the street sweepers in the city.

DR. W. C. DREESSEN, Washington, D. C. In regard to smoky cities, I hardly believe we are on comparable ground. Smoke is somewhat different from industrial dust, particularly in its size distribution. In regard to the air pollution of cities, I believe the concentrations are very much lower than 5,000,000 particles of a size usually encountered in industrial plants.

DR. R. R. JONES, Washington, D. C. There are some facts indicated in this paper which I would like to emphasize. First, the length of time required to develop this disease to the point at which such pulmonary disorder is revealed as was shown in the films presented. The patients had worked for many years, and with the exception of one discussed, all were still at work. This clearly shows that since anthracosilicosis develops slowly over a period of years, a positive diagnosis of the disease does not necessarily mean disability. Dr. Riddell of Canada in a recent article stressed a peculiarity of the

and scarcely any mention was made regarding this procedure until the recent publications by Grant² and McCarthy³ in 1935 recommended direct intraprostatic

injection through the panendoscope Townsend⁴ in 1936 reported further observations on intraprostatic injections

Chronic prostatitis is a very frequent clinical condition which too often resists intelligent and diligent prolonged treatment. Any method, therefore, that can

Fig 2—Normal dog prostate showing the normal histologic appearance and glandular arrangement of dog prostate

safely be applied to hasten the cure or shorten the course of this common ailment deserves careful consideration

Grant² has injected from 10 to 20 cc of 1 per cent aqueous solution of mercurochrome directly into the lobes of the prostate gland through a needle inserted perineally in more than 400 instances. He reports almost universal amelioration of symptoms and a rapidity of cure not usually obtained by other methods of treatment. He further states that this procedure has been carried out without a single untoward result in any instance.

McCarthy injected from 3 to 8 cc of colloidal silver solution into each lateral lobe of the prostate through

Fig 3—Dog prostate two weeks after injection of 2 cc. of 2 per cent mercurochrome. a chronic inflammation b fibrous tissue c areas of necrosis. Marked glandular destruction chronic inflammation and fibrosis

the urethroscope. This procedure was carried out in each of forty patients on from three to seventeen occasions. He states that all but two of these patients reported definite improvement and sixteen were discharged as clinically cured.

No mention is made in any published paper on the subject of intraprostatic injection of an attempt to determine what changes actually occur in normal prostatic tissue after it has been infiltrated with mercurochrome or colloidal silver. Grant merely states that at the outset of his work he "injected a few dogs' glands and they seemed none the worse." All exponents of this method seem to infer that the rationale of the procedure is based on the direct bactericidal effect of the injected solution for the organisms retained in the prostatic acini and ducts. Grant states that he does not attempt to say definitely how mercurochrome acts when injected into the prostate. It is his belief that "in this type of injection the mercurochrome acts with definite germicidal properties, and since it does remain in the gland for an extended period it prevents further bacterial growth. It does not seem likely that it acts in some obscure biological way as it does when injected intravenously. Indeed the entire basis of our hypoth-

Fig 4—Dog prostate two weeks after injection of 2 cc. of 2 per cent mercurochrome showing marked glandular destruction and fibrosis

esis is the introduction of some antiseptic directly into the seat of inflammation in an endeavor to check that process by direct action."

Townsend states that substances injected into the prostate diffuse throughout the gland and that since substances so injected find their way into prostatic blood vessels, no medicament should be introduced into the gland that will not be tolerated by the general circulation.

This study was undertaken to determine the early and late tissue effects occurring in the prostate gland of dogs after direct injection. Our present report deals only with those injected with mercurochrome solution and colloidal silver solution, the substance recommended by Grant and McCarthy in their recent publications. The effects of other drugs are also being studied and will be given in a later publication.

TECHNIC

The prostate gland in fully grown dogs being extra vesicular is easily isolated extraperitoneally in the post pubic space. An incision paralleling and slightly lateral

⁴ Townsend T. M. Intraprostatic Injections. J. Urol. 35: 75-82 (Jan.) 1936.

to the penis permits a muscle splitting incision and rapid exposure of the entire prostate without the necessity of any instruments or other traumatic application to the gland. Injection of the gland can be made under direct vision without disturbing any structures except a small amount of periprostatic fat on the

Fig 5—Dog prostate removed seven weeks after injection of 2 cc of isotonic colloidal silver. *a* marked fibrosis, *b* areas of normal glandular tissue. Marked destruction of glandular tissue replaced by fibrous tissue with occasional areas of rather normal gland tissue.

superior surface. The prostate in well grown dogs is apparently from one-third to one-half the gross size of the adult human prostate, with the urethra traversing the central portion. In injecting the prostate great care was taken to avoid any trauma that might excite tissue changes not comparable to the procedure in the human being. A small needle was used and only two sites of injection were made, one on each side of the gland. Care was also taken to avoid anything that suggested overdilatation of the gland and that might conceivably produce a pressure necrosis. On this account no injection exceeded 5 cc, while the average injection was 2 cc (1 cc on each side). That the drug diffuses readily throughout the gland is apparent on inspection. The needle was moved to include six areas in each instance, and the injection was made slowly. Very little or no leakage occurred from the prostatic capsule at the site of injection after the withdrawal of the needle. All operations were done under strict aseptic technic and under phenobarbital sodium anesthesia. Incisions were closed without drainage. Fourteen dogs were injected without a postoperative death, and convalescence was uneventful without febrile reaction or apparent difficulty in voiding. The dogs were killed at the required intervals and the entire prostate was removed en masse for gross and histologic study.

For the purpose of brevity the following general summary of the gross and microscopic changes found in the dogs' prostates removed at varying periods after injection, is given rather than a detailed protocol in each instance.

PROTOCOLS

The prostate removed seven days after injection of 2 cc of 2 per cent mercurochrome showed a gross adhesion of the periprostatic fat to a moderately thickened glandular capsule. These adhesions were strictly fibrous in character. The acini in some areas appeared to be totally destroyed while in other areas there was only partial destruction. In some regions the acini were replaced by areas of hemorrhage in others by cellular infiltration and in still others by fibrous tissue. Under

higher magnification the partial or complete destruction of the acini was more apparent. The remaining lumens were filled with cellular debris, erythrocytes and small lymphocytes, plasma cells and histiocytes. The septums between the acini were thickened with dilated engorged capillaries and an infiltration by fibroblasts, small lymphocytes, histiocytes and plasma cells. In brief then, these sections showed an active hyperemia, a scattered subacute inflammatory reaction with glandular destruction and an early fibroblastic proliferation.

The prostate removed fourteen days after the injection of 2 cc of 2 per cent mercurochrome showed only slight gross adhesion of the periprostatic fat to the thickened glandular capsule. There was an almost complete destruction of the glandular structure. Some areas were of necrotic tissue, others showed cellular infiltration, and still others were replaced by fibrous tissue. Under higher magnification this marked glandular destruction associated with fibrous tissue replacement was seen more clearly. Thus the specimen fourteen days after injection showed merely a more advanced stage of the changes noted after seven days.

The prostate removed sixty-three days after injection of 2 cc of 2 per cent mercurochrome showed grossly, and under low power magnification, similar but more advanced changes as compared with the glands removed seven and fourteen days after injection. Under high magnification there was partial or complete glandular destruction, a moderate and apparently decreasing cellular infiltration but a more marked fibroblastic proliferation.

INJECTIONS OF COLLOIDAL SILVER

The prostate removed fourteen days after injection of 2 cc of isotonic solution of colloidal silver showed grossly a very marked destruction of all acini, with areas of necrosis, fibrosis and cellular infiltration. Higher magnification revealed cellular debris, the remnants of a necrotic acinus and marked cellular infiltration. Under still higher magnification these infiltrating cells consisted of small lymphocytes, plasma cells, fibroblasts and histiocytes. Here again was observed a diffuse destruction

Fig 6—Dog prostate seven weeks after injection of 2 cc of isotonic colloidal silver solution showing marked glandular destruction and fibrosis.

of the glandular structure associated with a chronic inflammatory reaction and a beginning fibrosis of the gland as a whole.

The prostate removed forty-nine days after injection of 2 cc of isotonic colloidal silver solution showed a more marked gross reaction in the gland amounting to an almost complete destruction of all acini, subsiding evidence of chronic inflammation and a dense fibrosis of the entire gland. Under higher magnification there were only scattered remnants of the gland surrounded by a fibrous tissue mass.

The prostate removed seventy days after injection of 15 cc of nonisotonic colloidal silver presented marked glandular destruction with areas of necrosis, chronic inflammation and fibrosis. Higher magnification of a discrete inflammatory area showed partially destroyed acini which were filled with small lymphocytes, plasma cells and histiocytes. The septums separating the acini were thickened and densely infiltrated with these cells. As might be expected the inflammatory reaction after injection of nonisotonic colloidal silver was more prolonged and gave evidence of more severe reaction than in the case of the isotonic solution.

CONCLUSIONS

Intraprostatic injection in full grown dogs with solutions of mercurochrome and colloidal silver, causes chronic inflammatory reactions, scattered areas of necrosis and complete or partial destruction of the acini. Diffuse fibrosis of the gland occurs subsequently.

55 East Washington Street—4458 West Madison Street

ABSTRACT OF DISCUSSION

DR. EARL EWERT, Chicago Drs O'Connor and Ladd have portrayed graphically on postmortem specimens what must occur in man when chemicals are injected into the prostatic gland. The fibroblastic proliferation has persisted after sixty-three days, and this to our minds is one of the most important observations in this investigation. In other words, two months after the use of injected chemicals the resulting tissue reaction was still proceeding. On this basis I wonder whether the end result in some of these will not be a small, firm, scarred prostate, for instance total sclerosis of the prostate with the rigid contracted bladder neck, and hence a fibrous median bar as a sequel. No doubt many of these patients with chronic prostatitis are doomed to this condition eventually, but I think that a certain percentage will be hastened years ahead of time. In 1931 I injected intraprostatically a filtered broth culture of the gonococci as had been done by previous workers. I was impressed by several facts. First many infected prostates are harder than they feel. Hence diffusion of the injected material tends to remain in one site. The gland itself is small. This, then, tends to deposit much material in a smaller area with accordingly a greater local tissue reaction, favorable or unfavorable. Second, the needles bend because of the hardness of the tissue and hence the evident futility of massaging some of these glands. A more rational procedure seems to me to be that of G. J. Thompson and D. M. Davis of urethroscopic observation the scalloping of the stenotic rigid ducts by the cutting loop and the Collings cutter. This provides drainage, and I have observed that the fibrosis proceeding in these glands may be stopped with a resultant improvement in their symptoms. A chronically inflamed gland for many years has already a fibroblastic proliferation with ducts that are stenotic and draining poorly, and I feel that this type of gland can better be handled by providing adequate drainage by the urethra. Perhaps Grant and his co-workers select their cases more carefully and eliminate the old scarred prostates with preprostatic infiltrations. I have not injected any prostates with mercurochrome or other chemicals and I should like to know the results on these glands four or five years later.

DR. VINCENT J. O'CONNOR, Chicago We offer this paper before this section, where we feel it properly belongs, and while we make no attempt to draw a clinical analysis we wish to emphasize the importance of experimental control of a therapeutic procedure before it is recommended by urologists to the profession at large. It may be that the production of a certain amount of fibrosis in the large boggy chronically infected prostate is a good therapeutic procedure. From this experimental study it would seem that the beneficial clinical results credited to intraprostatic injection must be due to fibrotic obliteration of infected acini rather than to a localized sterilization of the injected tissues. These prostates in dogs were injected with a small amount of solution and yet the gross changes are severe and diffuse. These glands were normal and not infected at the time of injection and I believe that all of us would approach such a procedure using the solutions studied, with considerable deliberation and caution.

BONE GROWTH DISTURBANCE FOLLOWING HEMATOGENOUS ACUTE OSTEOMYELITIS

JOHN C. WILSON, MD

AND

FRANCIS M. McKEEVER, MD

LOS ANGELES

Medical literature of the past twenty years contains very little information relative to bone growth change, resulting from osteomyelitis in children. Speed¹ in 1922 called attention to the alteration in adolescent bones following pyogenic infection and made suggestions for their treatment. A review of sixty-four patients with ninety individual ul of infection, who suffered from acute hematogenous osteomyelitis leads us to believe that disturbances in the conformation of bone are relatively frequent. An attempt has been made to determine (1) the common variations in the contour of

Fig. 4—Percentage of total number of patients showing evident clinical growth disturbance.

the long bones and the bones of the feet, (2) the relationship of the location of the focus of infection in the individual bone to the subsequent growth disturbances and (3) the bearing of the time of surgical drainage on disturbances of growth.

The ninety foci of infection were distributed as follows: tibia thirty, femur twenty-nine, humerus ten, radius five, os calcis five, fibula three, metatarsals three, ulna two, phalanges two and clavicle one.

Fig. 6—Perimetric hypertrophy showing evidence of subperiosteal displacement at the end of the first three months. Perimetric hypertrophy limited by periosteal displacement. Note marked but incomplete reconstruction of shaft.

Infections of the vertebrae, scapula, ribs and bones of the pelvis have not been included. Accurate mea-

From the Orthopedic Department of Children's Hospital. Because of lack of space this article is abbreviated in *THE JOURNAL*. The complete article appears in the authors' reprints. Read before the Section on Orthopedic Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, May 14, 1922. ¹ Speed, Kellogg, Surg., Gynec. & Obst. 34:469 (April) 1922.

measurements of the amount of distortion were not possible. Osteomyelitis of the terminal phalanges was also excluded because the infection is by direct extension and not through the blood stream.

The individual bones comprising this study readily fall into two groups. The first one embraces the long bones with a diaphysis and one or more terminal epiphyses. There were fifty-nine cases in this group presenting eighty-five individual osteomyelitic infections. The second group includes five cases of hematogenous acute osteomyelitis of the os calcis. The os calcis grows by accretion and has no diaphysis or terminal epiphyses. The apophysis is comparable to the tibial tubercle and serves as a muscular attachment. The changes in contour of this bone are due to factors other than epiphyseal disturbance. The undeveloped but firmly attached periosteum of the os calcis influences the changes in shape that follow acute osteomyelitis.

AGE INCIDENCE

The onset of infection was in all cases prior to the twelfth year. The patients at the time of this report

Fig 7—Total number of infections producing lengthening of bones with distribution as to individual bones and amount of lengthening

were between 5 and 19 years of age. The largest group was between 13 and 19 years of age when they were last examined.

No patients were included in this survey who had not been observed for at least two years. One patient has been under observation for fourteen years.

CLASSIFICATION OF GROWTH DISTURBANCES

An attempt has been made to classify in a simple manner the changes that occurred in the long bones with one or more terminal epiphyses, as follows:

- I Primary variations
 - (a) Perimetric hypertrophy
 - (b) Lengthening
 - (c) Shortening
 - (d) Directional changes
 - (1) Coxa valga.
 - (2) Bowing anteroposterior and lateral
- II Secondary variations
 - (a) Disturbance of joint inclination
 - (1) Genu valgum
 - (2) Medial deviation of the ankle.
 - (3) Lateral deviation of the ankle.
- III Concomitant variations
 - (a) Compensatory lengthening of uninfected parallel bones
 - (b) Shortening and diminution of size of feet without infection in any of the component osseous structures

It is rather striking to note that perimetric hypertrophy followed all infections of the long bone in this group of patients. In eighteen of these patients the disturbance was slight, varying from 1 mm to 2.5 mm, but nevertheless was always demonstrable by roentgen examination. This condition could not be detected in the femur by clinical examination because of the well developed muscle covering. On the other hand, a small degree of distortion in the tibia, because of its superficial location, was easily detected without the aid of x-ray examination. Thirty-two of eighty-five infected long bones, or 37.65 per cent, escaped without a disturbance in length or direction. In other words, fifty-three, or 62.35 per cent, of infected long bones had obvious deformity due to disturbance in growth, which was easily detected by clinical examination.

Of the thirty-two foci that recovered without a disturbance of growth, eighteen, or 56.28 per cent, were operated on late after the tenth day of the infection, and fourteen, or 43.72 per cent, were operated on prior to the tenth day of the illness. This would seem to indicate that early drainage plays no part in the prevention of growth aberrations and, conversely, that deferring surgical intervention until the individual has an opportunity to localize the infection does not enhance the morbidity of growth disturbances.

Fig 8—Tibia lengthened 2.5 cm. There is no disturbance of the ankle joint inclination because of compensatory lengthening of the fibula.

PERIMETRIC HYPERTROPHY

A study of the roentgenograms of infected bones clearly indicates that perimetric hypertrophy is determined by periosteal displacement and is also limited by the extent of this displacement. A study of the roentgenograms in early stages of the disease will often

Fig 9—Total number of infections producing shortening of bones with distribution as to individual bones and amount of shortening

reveal the extent of periosteal elevation and from this a prediction may be made regarding the extent of this perimetric hypertrophy. This increase in the transverse diameter of the long bones occurs very rapidly during the first three months and then gradually subsides. While the bone tends to resume its normal conformation, the subperiosteal new bone never entirely dis-

appears. It is also of interest to note that areas from which the periosteum has been resected show no evidence of perimetric thickening. It was also observed that perimetric hypertrophy does not occur to a great degree in centrally placed Brodie's abscesses. This is due to the fact that the inflammatory reaction is not of sufficient degree to cause marked stimulation of the bone producing power of the periosteum. In eighteen

Fig. 11—Disproportionate bone growth of tibia and fibula due to premature closure of the distal tibial epiphysis. Mechanics of ankle joint markedly disturbed.

infections in which the perimetric hypertrophy did not exceed 0.25 cm there was little if any periosteal reaction. The centrally placed limited foci are included in this group. In fifty-six of the infected bones the perimetric hypertrophy ranged from 0.5 to 1.5 cm. In these instances the periosteal reaction was plainly demonstrable by roentgenogram and varied in degree

Incidence of Moderate and Marked Degree of Perimetric Hypertrophy

Perimetric Hypertrophy	Lesions	Periosteal Reaction	Time		
			Drained Early	Drained Late	No Operation
0 to 0.25 cm	20	None many central abscesses	2	17	1
0.25 to 1.5 cm	50	Moderate and marked	25	31	0
1.5 to 3 cm	9	Always very marked	5	4	0
Os calcis No perimetric hypertrophy	5	None	5	0	0

from moderate to marked. Perimetric hypertrophy was by actual measurement from 1.5 to 3 cm in thickness in nine of the infected bones. This was classified as extreme.

Fig. 12—A early infection three weeks after onset in upper third of femur. B thirteen months subsequent to infection right trochanteric epiphysis closed with beginning coxa valga deformity left trochanteric epiphysis not fused. C trochanteric epiphysis closed nine years after onset of infection permanent coxa valga deformity of right femur of marked degree.

The incidence of moderate and marked degree of perimetric hypertrophy was not materially decreased by early drainage of infected bones as indicated in the accompanying table.

The periosteum of the os calcis is firmly adherent and is stripped with difficulty by edema or infectious

exudate. Therefore, enlargement of the os calcis would not be anticipated because of the relationship that seems to exist between periosteal stripping and perimetric hypertrophy. The changes of contour in five cases of osteomyelitis of the os calcis were attributed to bone softening and muscle tension.

The activity of the periosteum in the production of new bone is of prime importance in the repair of defects due to sequestration and loss of substance through surgical intervention. These observations bespeak a word of warning to the surgeon and emphasize the importance of careful preservation of this important anatomic structure.

LENGTHENING

Eighteen of eighty-five infected long bones, or 21.18 per cent, showed an actual increase in the length of the bone involved.

The infection in all patients with bone lengthening was located in the diaphysis and not necessarily in juxtaposition to the epiphyses. In three instances of lengthening of the femur the infection in the shaft was located near the epiphysis of the trochanter major. As a result of the hyperemia caused by these foci the angle between the shaft and the neck of the femur was

Fig. 13—Femur with marked anterior and lateral bowing associated with actual lengthening.

markedly distorted, causing a coxa valga deformity. This deformity was of course responsible in part for the actual lengthening of the femur. This was specifically so in the patient who exhibited 5 cm of increased length of the leg.

Four of the eighteen patients with infections that produced lengthening of the long bones were operated on within ten days after the onset of the acute osteomyelitis. Drainage was instituted in fourteen at varying periods after the tenth day of the onset of the infection. We have been unable to discover any definite relationship between the time of drainage and the extent of disturbance when the infection is located within the diaphysis. An endeavor was made to correlate the time of drainage of the osteomyelitic infection with the extent of disturbance of bone growth. Our observations seem to indicate that the time of operation has no bearing on this later phase of the disease.

Elongation of the infected bone in an extremity in which there is a companion bone, such as the leg or the forearm is associated with an actual lengthening of the uninvolved bone. It is also of interest to note that this increasing length of the infected bone produces a corresponding elongation of the uninfected bone without disturbing the mechanics of the joint formed by the articular extremities of the bone in question. The abnormal growth of the infected bone

bone exerts a pulsion force which is distributed in such a manner that the longitudinal axis of the normal bone is not distorted

SHORTENING

Eighteen of eighty-five infections or 21.18 per cent, caused an actual decrease in the length of the involved bone

The focus of osteomyelitis which caused interruption of growth was located in the diaphysis adjacent to the epiphyseal cartilage. X-ray examination showed the epiphyseal line to be interrupted, narrowed or prematurely closed at the periphery. The greatest amount of shortening, which was 6 cm., occurred in a femur in which the infection was complicated by a pathologic fracture. The shortening was due in part to a loss of substance at the point of fracture, but a considerable amount of shortening was nevertheless due to premature closure of the distal femoral epiphysis.

Five of eighteen infections, or 27.7 per cent, which caused shortening were drained within the first ten days. Thirteen, or 62.3 per cent, were drained later.

Fig 14—Knock knee deformity due to premature closure of the lateral half of the femoral epiphysis

This evidence is inconclusive but suggests that the time of drainage has little to do with the shortening. There were four small central lesions in the epiphyseal plate. These show at the present time roentgenologic evidence of excellent repair. Shortening or directional disturbance of the growth of bone did not ensue because of the fact that the infected areas did not encroach on the epiphyseal margins. Three of these foci of infection were located in the end of the radius and one in the lower end of the ulna.

The physiologic disturbance in the extremity supported by two bones is of course pronounced when infection occurs in one bone. The rate of growth of the uninjured bone is not retarded, in fact, in some cases growth seems to be accelerated. The rapidly growing uninfected bone acts as a pulsion force, bending the shortened infected bone. On the other hand the shortened infected bone acts as a bow string, or traction force, causing bending of the rapidly growing uninjured bone. This condition was noted in the forearm and in the leg.

Under these circumstances the mechanics of the joint formed by the paralleling bones will be markedly altered, owing to medial or lateral tilting of the articular surfaces. This is particularly noted in the ankle joint. A disturbance corresponding to Madelung's deformity was seen at the wrist even though there was no tilting of the joint surface.

COXA VALGA

Growth of the upper end of the femur occurs at the capital and trochanteric epiphyses. In lower animals this is one epiphysis, but with the assumption of the upright position and the development of a well defined

joint capsule a complete division occurs in the epiphyseal plate. This survey reveals that infections in the upper end of the femur which involve the trochanteric epiphysis, causing its premature closure, result in a coxa valga deformity of the neck of the femur. The reason for this is quite evident when one considers the fact that growth on the medial aspect of the neck of the femur will continue at a normal or accelerated rate.

Fig 15—Knock knee deformity. A due to medial bowing of the lower third of the femur. B due to medial bowing of the upper third of the femur

while that on the outer aspect of the femur is retarded, owing to a disturbance in the trochanteric epiphysis. This coxa valga deformity will result in actual lengthening of the femur with concomitant pelvic tilt and scoliosis.

BOWING OF THE LONG BONES

Four patients were found to have definite anterior bowing in the lower third of the femur, and in one patient anterior bowing developed in the lower third of

Fig 16—Lateral deviation of ankle with disturbance of weight bearing due to growth disturbance in the lower tibial epiphysis.

the tibia. This deformity was quite marked and did not require roentgen examination for its detection. In two instances the femur showed an actual lengthening. The tibia was also elongated.

LATERAL BOWING

Slight degrees of medial and lateral bowing were frequently evident in the roentgenograms. This bowing was usually at the operative site and was not clinically

demonstrable A few instances of medial bowing of single bones caused a knock knee deformity Lateral bowing was observed twice in the bones of the forearm While this bowing of the long bones is classified as a growth disturbance, it differs somewhat from those described in connection with epiphyseal disturbances This bowing is, however, a definite clinical entity and is thought to be due to muscle pull on bones, which because of infection, have lost some of their normal tensile strength

GENU VALGUM

Knock knee deformity was present in ten cases as a result of infection involving the tibia or femur It was observed that it develops either from a direct involvement of the epiphysis or from its unilateral stimulation The stimulation of the medial half of the distal epiphysis of the femur will cause an overgrowth of the medial femoral condyle and a knock knee deformity This was present in four patients A retardation or premature closure of the lateral half of the distal femoral epiphysis will also cause a knock knee deformity This creates an imbalance in growth so that the normal activity of the medial half of the epiphysis is sufficient to produce a knock knee deformity This was found in one instance Medial bowing of the lower third of the femur caused knock knee deformity in one instance because of the abnormal line of weight bearing For the same reason, medial bowing of the upper third of the tibia caused a knock knee deformity in four patients It also may be presumed

Fig. 17—Distortion of os calcis due to compression without perimetric hypertrophy

that a genu valgum deformity will result from a premature closure of the lateral aspect of the upper tibial epiphysis It might also result from a stimulation of the medial half of the upper tibial epiphysis due to circumjacent infection There was no instance of this distribution of infection in this series of cases Lateral deviation of the ankle joint may follow as a result of a premature closure of the lateral half of the lower tibial epiphysis as illustrated by figure 16

OS CALCIS

The reaction of the os calcis to infection differs sufficiently from that of other bones to warrant special consideration It was noticed that small abscesses may occur in the body of the os calcis and result in recovery without change in shape or consistency of the bone

Perimetric hypertrophy does not follow hematogenous acute osteomyelitis of the os calcis because of the

Fig. 19—Graphic illustration of percentage of small feet without infections in bones of foot. Amount of shortening of feet with location of infection

adherent periosteum Infection of the calcaneal apophysis did not produce shortening of the infected bone or of the foot, but extensive infection of the body of the os calcis did cause shortening both of the infected bone and of the entire foot This may be explained by the fact that growth of the os calcis is by accretion. The calcaneal apophysis is comparable to the tibial tubercle in that it serves only as a muscular attachment. The os calcis did exhibit a boat-like deformity with broadening despite the fact that weight bearing was excluded This deformity is attributed to gradual compression of bone, softened by infection, which is unable to withstand normal muscle tension of the powerful gastrocnemius-soleus muscle group

METATARSAL BONE AND PHALANGES

The metatarsal bones and phalanges show a great ability to regenerate and restore the normal contour This is despite the fact that the osteomyelitic infection is associated with extensive destruction, sequestration and perimetric hypertrophy Even though an epiphysis may be destroyed or the epiphyseal line of an individual metatarsal bone or phalanx fused at a premature time the rate of growth of paralleling and contiguous bones is not changed Directional disturbances are not produced Shortening of the infected bone may follow but this influences only the growth and development of the individual digit There is perhaps one exception and that pertains to extensive infection of the first metatarsal bone Because of its location this may lead to some disturbance in contour of the medial border of the foot causing faulty and painful weight bearing

SMALL FEET

Decrease in the size of the foot was present in 59 of fifty-nine patients or 10.2 per cent despite the fact that the bony structure of the foot was entirely free from infection Two instances of this growth disturbance followed a lesion of the tibia, one in extensive diaphyseal infection and the other in the lower third of the shaft Small feet were found in 10

instances in which a focus was located in both the tibia and the femur of the involved side. Two followed infections in the upper third of the femur. The difference in the size of the feet was sufficient in four instances to require special shoes.

The explanation of this disturbance of the growth of the foot is not clear. Patients in whom it occurred were not subjected to prolonged inactivity, and the extremities were not bound in plaster-of-paris dressings for unusually long periods. In fact, the term of splinting for some of the patients in whom small feet were found did not exceed eight weeks.

SUMMARY

Fifty-nine patients under 12 years of age with eighty-five individual foci of acute hematogenous osteomyelitis in long bones and five patients with acute hematogenous osteomyelitis of the os calcis were followed for periods of from two to fourteen years.

1 Fifty-three of eighty-five foci, or 62.35 per cent caused growth disturbances that were obvious by clinical examination.

2 Perimetric hypertrophy was present in 100 per cent of infections in long bones.

3 Actual lengthening of long bones resulted in eighteen of eighty-five infections, or 21.18 per cent. The infections that resulted in lengthening were always located in the diaphysis and left the epiphyseal line undamaged.

4 Actual shortening of long bones resulted in eighteen of eighty-five, or 21.18 per cent. The infections that caused shortening in all instances were in the region of the epiphyseal line, and premature changes in the epiphyseal lines were evidenced by roentgenogram.

5 Infection in proximity to the trochanteric epiphysis of the femur causing premature closure of the epiphyseal line resulted in the occurrence of *coxa valga* deformity adequate to cause actual lengthening of the femur.

6 Anteroposterior, medial or lateral bowing due to muscle pull on bones decalcified by infection was common.

7 Disturbances of joint inclination with severe alteration of joint mechanics resulted from bowing of the long bones adjacent to the joint, or from stimulation or retardation of a portion of the epiphyseal zone of a bone entering into the formation of a joint.

8 Retardation of the growth of the entire foot resulted in six of fifty-nine patients, or 10.2 per cent, in whom the bones of the foot were entirely free of infection.

9 The metatarsal bones showed great ability to reconstruct their normal contour after severe disturbances. The adjacent metatarsal bones were not influenced by growth disturbance in their neighboring bones.

10 Perimetric hypertrophy did not occur in the os calcis. Compression and broadening of the os calcis followed extensive infections of the body and resulted from muscle tension.

11 Early operative intervention in this series of osteomyelitic infections did not decrease the frequency of growth disturbances.

1136 West Sixth Street.

ABSTRACT OF DISCUSSION

DR D B PHEMISTER, Chicago. It is well that the authors have called attention to this condition because it has not received sufficient consideration. As they pointed out, the most important disturbance that arises is arrest of longitudinal growth of the shaft. That may be complete or partial. I want to call attention to the fact that partial destruction of the epiphyseal cartilage line may not result in arrested longitudinal growth. I have seen a few instances of osteomyelitis involving the metaphysis in which an abscess perforated the central portion of the cartilage into the epiphysis. Drainage of the abscess by decortication of the metaphyseal portion has in some cases resulted in healing without disturbance of longitudinal growth, but if the cartilage plate is destroyed at the periphery there is apt to be partial growth arrest with curvature and shortening of the bone. Growth arrest is relatively frequent at the upper end of the femur. If it is at the capital epiphysis and develops in young children there may be considerable upward growth of the greater trochanter, but in older children this is not the case. Osteomyelitis of the ilium may extend into and destroy the epiphysis of the bone along the sacro-iliac or hip joint, where it consists simply of a layer of articular cartilage. This results in growth arrest of the ilium with oblique contracture of the pelvis with elevation of the acetabulum. In the female there may be difficulty in labor from the pelvic deformity.

ACUTE HEMATOGENOUS OSTEOMYELITIS

AN ANALYSIS OF SEVENTY-FIVE CASES

ROBERT CRAWFORD ROBERTSON, M.D.
Orthopedic Surgeon, Baroness Erlanger and Children's Hospitals
CHATTANOOGA, TENN.

The essential pathologic condition in acute hematogenous osteomyelitis is a blood stream infection complicated by local infection of one or more bones. Within the past fifteen years the clinical trend has been toward early diagnosis and prompt surgical drainage of an increasingly conservative type. Diaphysectomy and tunneling have been largely replaced by drilling and removal of a cortical window at the

Fig 1—White girl aged 13 years. Cortex drilled and window removed sixty hours following onset under local anesthesia. Subperiosteal and subcortical abscess found. A Nov. 2, 1933, one month after drainage. Localized area of destruction. B March 12, 1935, thirty months after drainage. Bone well healed without sequestration. Wound healing time two and one-half months.

earliest possible moment. Early drainage is advocated on the grounds that infection first occurs within the medulla, usually in the metaphyseal region, from which it follows the lines of least resistance, resulting in extensive necrosis and subsequent sequestration. This belief is supported by the clinical observations of

Read before the Section on Orthopedic Surgery at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 14, 1936.

Starr¹ and the experimental work of Robertson² and Kistler³. By early drainage of the bone this destruction is thought to be prevented or minimized. On the other hand, Wilensky⁴ contends that the pathologic condition follows embolism and thrombosis within some portion of the circulatory system of the bone

Fig 2—White boy aged 12 years. Cortex drilled and window removed five days following onset. Subperiosteal and subcortical abscess found. A Oct 3, 1932 five days following onset. Localized area of decreased density. B Nov 5, 1932 one month after drainage. Small sequestrum within sharply localized area of destruction. C Aug 31, 1934 twenty months after drainage. Bone well healed with spontaneous extrusion of sequestrum. Wound healing time twelve months.

He states that a fluctuant abscess is the only indication for surgery during the acute state, as early drainage does not remove the exciting cause while by conservatism many operations are avoided.

Fig 3—White girl aged 2 years, Sept 5, 1934 four months after drainage of hip. Symptoms of sixty-four hours duration. Site of infection, femoral neck. No growth recovered from blood and wound. No sequestration. Wound healing time two months.

The objectives of treatment are the saving of life and limb and the healing of the infected bone with minimum delay. Healing without sequestration is the result to be desired. Published series report a widely

varying mortality rate of from 15 to 26 per cent, averaging about 12 per cent. Although the statement is made by many authors that early operation results in healing without sequestration, no report of a series recording such results has been found. Reports of series analyzing mortality, sequestration and healing time should be of value in determining the clinical merits of early and late surgical drainage.

In this series of seventy-five successive, unselected private and clinical cases that I have treated within the past nine years, only definitely acute, hematogenous pyogenic cases are included. While it is believed that the pathologic condition present is the true criterion of acuteness rather than the duration of the disease, it was found necessary to select some time limit in determining acuity. Twenty-two days was arbitrarily chosen as all cases that could be considered acute from a pathologic and clinical point of view fell within this limit. To minimize the possibility of including cases of primary and extension types, the small bones of the hand and foot and the mandible were excluded. The principle

Fig 4—White boy aged 8 years June 4, 1932 three weeks after drainage of hip. Symptoms of seven days duration. Site of infection, femoral neck. No growth recovered from blood or wound. No sequestration. Wound healing time two months.

of early drainage was followed in all. A follow up of from six months to eight years has been obtained in each case. The cases comprising the series are divided on the basis of results into four groups.

In the series 61.3 per cent were males. Although all ages are represented, 72 per cent of the cases occurred between the ages of 5 and 15 years.

The average yearly admission to the general hospital (Baroness Erlanger) is 6,242, of which 26.3 per cent is Negro. The average yearly admission to the Children's Hospital is 1,062, of which 17.4 per cent is Negro. Both hospitals are operated by the city and county and have proportionately large charity services. It is felt that the small ratio of Negroes in this series (6.3 per cent) indicates a relative racial immunity in this section.

Definite predisposing infection was not found in 45.3 per cent and definite predisposing trauma was considered absent in 62.6 per cent. In the group considered definitely traumatic is included a fracture epiphyseal separation of the proximal end of the humerus in a Negro boy aged 15 years. Two days

following the fracture, symptoms of acute local infection appeared. Fracture and epiphyseal separation preceding the onset of acute symptoms have been mentioned by Rose and Carless,⁵ Robertson² and Beekman⁶.

The distal end of the femur or the proximal end of the tibia was involved in 45.3 per cent. This combination has been previously noted and is con-

sidered by Beekman⁶ to be the result of frequent epiphyseal strains in this area. Involvement of two bones was found in 4 per cent of the group on admission to the hospital.

Pathologic dislocation of the hip was present in a girl 10 months of age with involvement of the femoral neck of twenty-two days' duration. A soft tissue abscess was present. Shelf operation was performed two years after onset without exacerbation.

A staphylococcus was found singly in 69.3 per cent of wounds and in combination with a streptococcus in one additional case. It occurred singly in 24 per cent of blood cultures and in combination with a streptococcus in one additional case.

Striking contrast between the groups occurs in physical and roentgen examinations. Pain on firm local bone pressure was the predominant finding in 63.1 per cent in group I and in 4.7 per cent in group III, while fluctuation was found in 31.5 per cent (one half of whom were under 2 years of age) in group I and in 71.4 per cent in group III. Groups II and IV were more evenly divided.

Roentgenograms were considered negative in group I in 84.2 per cent, while in group III only 7.6 per cent were so interpreted. Early roentgen changes were seen

in 66.3 per cent of group II and in 25 per cent of group IV as early as the fifth day and were absent as late as the fourteenth day following onset in one case.

The average duration of symptoms in group I was materially less than in group IV and was approximately half that of groups II and III. The average duration in infants under 2 years of age in group I was nearly one-third greater than any other group.

In four cases, diagnosis was not considered definite on the first examination. Traction, local heat or aspiration was utilized on admission and surgical drainage deferred until the diagnosis was considered definite.

The type of drainage employed in seventy-six operations on the seventy-five patients during the acute state varied widely with the individual case. Soft tissue abscesses when present were drained and the underlying bone was not opened. Subperiosteal abscesses were incised, the underlying cortex was drilled and a cortical window was removed. When subperiosteal pus was not found the cortex was drilled, and in six of seven such cases a window was also removed. In the seventh, only drilling was performed. Repeated joint aspiration without lavage was attempted in six cases. In one it was successful, in the others subsequent surgical drainage, in one case as late as the twenty-second hospital day, was considered necessary. When associated bone and joint disorder was found, the pathologic condition of the bone was treated on the foregoing principles, and the joint was incised only if definitely purulent material was obtained on aspiration.

In three patients, aged 40, 27 and 13 years, drainage was performed under local anesthesia. In the two adults (one a physician) the tibia was involved with symptoms of twenty-two and forty-eight hours' duration respectively. Subperiosteal exposure of the bone at the site of localized tenderness gave no relief. When the cortex was drilled at this level, both voluntarily stated that immediate local relief was obtained. No gross pus was found in either, but culture of the medulla was positive in both cases. In the child the

distal end of the femur was involved with symptoms of sixty hours' duration. A subperiosteal abscess was incised without relief of pain. The cortex was drilled, with release of pus under pressure, and marked immediate relief was obtained. Culture from the wound was positive. A cortical window was removed

in each case following drilling. These few experiences were so striking that cortical drainage has subsequently been performed as a routine except in the face of soft tissue abscess. Postoperative treatment in all cases of this series was by the Orr method or a slight modification.

In group I 68.4 per cent of the cases presented evidence of joint infection in contrast to 2.3 per cent in group III and 37.5 per cent in group IV. It is considered probable that this complication with its initial severity of local symptoms, facilitated early diagnosis and hospitalization in contrast to the cases in which it was absent.

A man aged 43 with involvement of the femoral head and a woman aged 64 with involvement of the tibia and fibula in the distal ends are atypical in that the acute symptoms apparently arose from activation of a low grade lesion of Brodie's type following trauma although no previous history of local pain

could be obtained. In all cases in which a subperiosteal abscess was found, the underlying bone showed granulation tissue when opened.

Beekman⁶ reports two acute cases of the tibia with involvement of both ends of the bone and normal medulla intervening and considers both lesions of probable hematogenous origin. One similar case likewise involving the tibia was found in this series necessitating a second drainage of the opposite end of the bone. At subsequent sequestrectomy long sequestrums were found in each end of the bone with

granulation tissue throughout the central portion of the medulla. It is felt that this is probably best explained by retrograde thrombosis plus infection, although the possibility of hematogenous origin of both lesions and direct extension of infection cannot be eliminated. Metastatic lesions were most frequent in group III which concurs with the experience of Wilson⁷

McKeever⁷ Pathologic fracture occurred twice in the distal end of the femur while in a spica cast, probably the result of the cast becoming loose following decrease of swelling, and once in the tibia during attempts to correct an equinus following incision of a soft tissue abscess

* Under 1 year of age

† Tibia original finding 48 hours after onset subperiosteal abscess distal end. Subcortical abscess proximal end drained 48 hours later. Staphylococcus aureus recovered from blood and wounds.

‡ Subsequent amputation

§ Thirty three cases now arrested. Healing time from 1 to 36 months average 23 4 months

The healing time in group I was roughly one-fourth that of group II and one-eighth that of group III

Amputation was performed in one case in group I because of a painful unstable knee following extension to the joint from the proximal end of the tibia. For occupational and economic reasons this was desired by the patient and would probably have been necessary at a later date regardless of his wishes

Serous effusions are not considered to be joint infections and are not included. Only those cases in which gross pus was obtained and subsequent x-ray examination revealed destructive lesions of bone adjacent to an epiphyseal line in part at least intracapsular, are reported as suppurative arthritis of bone origin

7 Wilson J C and McKeever F M. Hematogenous Acute Osteomyelitis in Children. J Bone & Joint Surg 18: 328-332 (April) 1936

Bisgard⁸ reports this complication in 19.3 per cent of a series of 217 cases of acute and chronic osteomyelitis at the University of Chicago Clinics

Adjacent suppurative arthritis of proved bone origin occurred in 24 per cent of the cases of this group. The average age (14.9 years) was in excess of the series age (10.1 years). The average duration at operation (79 days) was appreciably under the series duration (96 days). The mortality rate (22.2 per cent) was more than double that of the series (10.6 per cent). The only amputation occurred in this group

The hip was involved in 55.5 per cent of the cases in which this complication occurred

Diagnosis of the underlying bone lesion in the majority of cases was made by roentgenograms subsequent to operation. Drainage of the involved joint constituted the only drainage of the underlying bone lesion except when pathologic changes in adjacent bone made additional drainage necessary. Diagnostic aspiration was done as a routine. Lavage was not attempted in any case in this series

Positive cultures were obtained from the joint in eleven cases (61.1 per cent) of the series and in all cases of groups III and IV in which the complication

thirteen cases. On cultural comparison it was found that joint cultures remained sterile in 53.8 per cent, while bone cultures were sterile in 16.6 per cent.

Cofield⁹ noted the frequency of sterile joint cultures in septic arthritis. Cotton¹⁰ believes that joints are relatively tolerant to infection. Pearson¹¹ feels that the fluid in such joints is at first serous and sterile but will become purulent if neglected. Reich¹² states "If repeated aspiration and lavage are unsuccessful the condition is undoubtedly the result of an osteomyelitis." He attributes the frequent negative joint culture to some attenuating action occurring within the joint. Beekman¹³ observes that further extension within the bone is unlikely if an early metaphyseal lesion ruptures into a joint and that free drainage of the involved joint is the only operative procedure required.

It is felt that the involvement of joints from adjacent areas of bone infection aids mechanically in decompressing the bone, thereby decreasing bone destruction. It seems probable that such involved joints possess bactericidal properties the nature of which is unknown at present. Experimental work should here prove of value.

In this series the female mortality exceeded that of the male by more than 50 per cent. A staphylococcus was recovered on blood culture, alone or in combination with Streptococcus haemolyticus, in 75 per cent of the cases within this group. Death occurred within one week of the onset in three fourths of the cases. Two of the cases were of the fulminating type, in which death apparently resulted from the overwhelming intra-articular infection. In retrospect the wisdom of early drainage in these two cases is questioned. In four of the remaining cases, blood cultures were persistently positive and death resulted from general sepsis.

The mortality in the group with one or more positive blood cultures was 28.6 per cent. No intravenous medication other than repeated blood transfusion was given. This was done in the room or ward as part of the general policy of local and general rest. General treatment was otherwise symptomatic. Secondary abscesses were drained in the ward or room where fluctuation developed. The low mortality rate and the high percentage of positive blood cultures in this group resulted in constant checking of culture technique and comparison of culture reports with the clinical picture without discovery of gross error or discrepancy. In view of the fact that in nine cases only the admission culture was positive and subsequent cultures were repeatedly negative, and because of the average short duration of symptoms on admission, it is felt that many of these cultures were obtained during the phase of primary transient bacteremia. Early drainage precluded more than one preoperative blood culture. Of the twenty-one cases in which a positive blood culture was obtained on admission, all were treated by surgical drainage. Six patients died, while in the remaining fifteen cases subsequent negative cultures were obtained. In no case presenting a negative blood culture on admission was a positive blood culture obtained subsequent to operation.

CONCLUSIONS

- 1 In children under 2 years of age the clinical course of the disease varies widely from that of adults.
- 2 The American Negro appears to be relatively immune to the disease in this section.

TABLE 9—*Cultural Comparison of Groups With and Without Adjacent Suppurative Arthritis on Admission*

16 Group I No Sequestration (19 Cases)	With Joint Involvement (13 Cases)	Without Joint Involvement (6 Cases)
Ages	10 mos-64 yrs (av. 15.4 yrs)	6 wks-40 yrs (av. 16.1 yrs)
Duration of symptoms prior to drainage	20 hrs-22 days (av. 7.8 days)	22 hrs-8 days (av. 3.1 days)
Positive cultures	6	5
Days from onset to operation	2-7 days 17 days (av. 8.7 days)	22 hrs-5 days (av. 3.2 days)
Negative cultures	7	1
Days from onset to operation	20 hrs-22 days (av. 6.8 days)	2.5 days

3 Acute hematogenous osteomyelitis must be considered when pyrexia and localized pain on bone pressure coexist in the absence of an obvious cause.

4 The majority of the best results were obtained by drainage of the bone within one week following the onset. The mortality rate was also highest in cases in which drainage was instituted within this period.

5 The pathologic changes present, while usually directly proportionate to the duration of the symptoms, are influenced by many other factors.

6 Acute, pyogenic, suppurative arthritis should be considered to be osteomyelitis of an adjacent bone until proved otherwise

7 Clinically, joints are more resistant to infection than bone and apparently possess marked bactericidal properties

ABSTRACT OF DISCUSSION

DR. EDWIN W. RYERSON, Chicago The impression that I gain from Dr. Robertson's paper is that it will be a very useful study in the tabulation of what every one hopes will be many series of similarly analyzed cases and in a few years, when a number of investigations from different localities and clinics have been made, orthopedic surgeons will be in a better position to judge in an individual case as to the treatment. Nothing can be done about the prevention. There are some points of interest, and one of them is the tenderness on local pressure not sudden and sharp but rather soft and continuous. A few months ago I saw a little girl in Chicago who complained of pain around her knee. Movement in the joint was unimpaired, but she had a fever of 102 and on deep pressure over the

the incidence in the Negro race, I would like to substantiate. For some reason, I do not know what osteomyelitis seems to be less frequent in the Negro, at least in Memphis, than among the white people

DR. ROBERT L. PRESTON, New York I am interested in the 24 per cent of cases that were complicated by acute suppurative arthritis. For the past two years I have been studying the problem of experimental acute staphylococcal suppurative arthritis, in an attempt to find out what factors are responsible for the bad results that are so frequently seen. I feel that the facts brought out by an analysis of observations have a direct bearing on the problem of acute hematogenous osteomyelitis. In the course of this experimental work a measured amount of *Staphylococcus aureus*-haemolyticus was injected into the knee joint of rabbits. The typical acute suppurative arthritis picture developed, marked swelling with distention of the joint with pus, disorganization of the joint, erosion of the articular surfaces and spread of the infection into the surrounding bones and soft parts. In those cases in which treatment was delayed, there was a tendency for metastatic abscesses to develop in the lung, heart, liver and kidneys, and for metastatic bone and joint infections to appear. As injection of the knees of other animals continued with available strains

* Mortality rate series 10.6 per cent (male 8.7 per cent female 13.8 per cent)

lateral condyle of the femur she winced. Although there was little evidence in the roentgenogram of any lesion an operation was advised and revealed a focus of osteomyelitis exactly like Dr. Robertson's first picture. That is one important point. Another point that interested me was his conclusion that extension of an osteomyelitis adjacent to a joint, into the joint, decompressed the original focus and made the patient's pain less. So far as I know, that is an original idea. I shouldn't advise as a method of treatment that in order to decompress an abscess one should bore a hole into the joint and into the abscess. But it is interesting because it shows that this young man has thought about his cases and has reasoned about them. Another point of interest was the low incidence of osteomyelitis in the Negro race. That I had not known before.

DR. JOSEPH I. MITCHELL, Memphis, Tenn. Dr. Robertson has presented proof of the value of early diagnosis and treatment in acute osteomyelitis. Early blood culture studies have been made and in a large proportion of his cases the cultures were positive. The inciting cause of osteomyelitis is bacteremia, in some cases this bacteremia persists or becomes septicemia. I think that is the explanation of the high mortality rate in this disease. When the bacteremia is transient subsequent blood culture is negative and the patient will, as a rule, recover. When septicemia ensues the patient stands a very good chance of losing his life. The largest percentage of the fatal cases occurs as Dr. Robertson said, within the first two weeks. The other point that he brought up, about

of *Staphylococcus aureus* there began to be an entirely different picture. With some of these strains the local joint damage was negligible but the animals died because of a marked toxic degeneration of the kidney, heart muscle and gastro-intestinal tract. In this type of infection, metastatic abscesses were never seen. Repeated inoculations of a large series of animals with either the toxic or the abscess strains of *Staphylococcus aureus* continued to produce definite, characteristic clinical pictures. It became evident that some strains of *Staphylococcus aureus* were involved which produced a markedly destructive and invasive lesion at the site of inoculation and had a tendency to produce metastatic abscesses, and other strains of *Staphylococcus aureus* which produced but little local damage at the site of inoculation and killed the animal by overwhelming toxemia. This toxic clinical picture is much like that produced by such exotoxin-producing organisms as *Bacillus diphtheriae*. This analogy is further substantiated by the fact that a virulent exotoxin could be isolated from these strains and could not be isolated from the abscess-producing type of *staphylococcus*. Since these two markedly different pictures characteristically result from infection with different strains of *Staphylococcus aureus*, it is evident that the therapeutic indications in staphylococcal infections must differ widely. These studies seem to indicate that the local and systemic damage following acute staphylococcal suppurative arthritis does not depend on whether or not joints are particularly resistant to infection or whether synovial fluid

has bactericidal properties. It seems to depend on whether the joint is infected with the toxic or abscess type of *Staphylococcus aureus*.

DR. JAMES B. WEAVER, Kansas City, Mo. It has long been known that the staphylococcus produces an exotoxin which is hemolytic and necrotizes tissue. It has been known for some time that adults have in their blood stream a certain amount of natural antitoxin to the staphylococcus. Children very rarely have any natural antitoxin. Patients suffering from deep staphylococcal infections have a large amount of antitoxin in the blood stream, as a rule. A method of measuring this antitoxin has been in use for several years. It is simple, much more simple than the Wassermann test and is carried out something after this manner. A rack of test tubes is set up in which there is 1 cc. of washed rabbit cells used as an indicator. A definite amount of antitoxin and various dilutions of the patient's serum are placed in each tube. After sitting in the water bath for a while, it is removed to the refrigerator. When the toxin is in excess of the antitoxin in the patient's serum, hemolysis takes place, and the reading is made in the amount of dilution in the patient's serum. I don't know when a case of osteomyelitis is cured. These cases should be reported as five year cures, ten year cures and so on. Most of the deaths from acute osteomyelitis occur in the first ten days. It is my belief that these deaths are due to toxemia and not to bacteremia. Pathologic specimens in these cases show destruction of vital organs due to toxemia and not to destruction of vital organs but to bacterial invasion.

THE RÔLE OF ALCOHOL IN CIRRHOSIS OF THE LIVER

A CLINICAL AND PATHOLOGIC STUDY BASED ON
FOUR THOUSAND AUTOPSIES

RUSSELL S. BOLES, M.D.

AND

JEFFERSON H. CLARK, M.D.

Visiting Physician and Chief of Laboratories, Respectively, Philadelphia
General Hospital
PHILADELPHIA

Cirrhosis of the liver is a fairly common chronic disease, presenting in its later stages a well recognized clinical and pathologic picture. In its early stages, while the histologic aspects may be recognized with reasonable accuracy, the clinical diagnosis is seldom evident and frequently is based more on presumption than on fact.

Great diversity of opinion exists regarding the etiology of the disease, from both a clinical and an experimental point of view. In a general way it is believed to be the result of various toxic and infectious agents which cause a destruction of the liver cells and produce a proliferation of the connective tissue that ultimately leads to fibrosis of the organ.

For many years alcohol has been considered one of the commonest causes of cirrhosis of the liver so much so that the term "portal cirrhosis" is used almost synonymously with "alcoholic cirrhosis" and as such heads the list in most classifications of the disease. Other factors considered in the etiology are syphilis, tuberculosis, diabetes and such acute infections as measles, scarlet fever, typhoid and pneumonia. Such substances as copper, arsenic, lead and silver, bacterial toxins especially of intestinal origin, condiments such as chilies and spices and a deficiency of vitamins A, C and D and fats and proteins in the diet all, at one time or another, have been suspected of causing the disease.

Experimentally, it is generally accepted that alcohol alone will not produce cirrhosis of the liver. However, when administered in combination with other toxic substances, cirrhosis has been produced.

In recent years there has been growing an increasing tendency to dispute the status of alcohol in the development of cirrhosis. It was with this in mind, especially, that the present investigation was undertaken. We wished to determine the incidence of cirrhosis of the liver, based on histologic evidence, as it occurred in a large general hospital—the ratio of age, sex and race and, more especially, the relation borne to the disease by alcohol and the acute infections, and by syphilis, diabetes and tuberculosis. For this purpose 4,000 autopsies were studied. They were all performed during the period from March 1933 to July 1935. The period happened to cover approximately the first two years following the repeal of prohibition. Whether the fourteen year era of prohibition preceding this period, during which there presumably was less drinking of strong spirits, might be of influence in the facts presented, is debatable.

We recognize with others the inadequacy of the terms portal, biliary, fatty, and the like in classifying cirrhosis, and the desirability of a classification based on etiology. Considering the uncertain state of knowledge, however, concerning the etiology, the difficulties inherent in such a classification are obvious. While we do not presume to offer a new classification for the cirrhoses and will present our cases in accordance with the more familiar terminology, we believe that a more accurate and descriptive classification of the disease, based at least on our observations, would be as follows:

1 *Circulatory*—The result of prolonged failure of the circulatory system incident to advanced myocardial degeneration and leading to the so called red atrophy of the liver or cardiac cirrhosis.

2 *Degenerative*—The usual portal or atrophic type, which results from a degeneration or necrosis of liver cells, and proliferation of fibrous tissue and bile ducts, often accompanied by an extreme degree of fatty infiltration of the remainder of the liver parenchyma. This type is generally attributed to the effect of alcohol or other toxic agents.

3 *Infectious*—The result of a continuous low grade infection probably brought to the liver from some portion of the gastro-intestinal tract or possibly from the spleen. It exhibits in the periportal spaces increased fibrous tissue, which is sparsely or densely infiltrated with lymphocytes and plasmocytes in particular. Bile duct proliferation is not so marked.

4 *Obstructive*—Characterized by bile stasis, increased fibrous tissue and bile duct proliferation, the latter often extreme and the result of obstruction to bile flow (gallstone compression from cancer cells, primary and metastatic, and so on).

5 *Pigment*—The deposition of abnormal pigment as carbon, hemosiderin or hemofuscin, which produces by mechanical irritation essentially the same histologic picture that is seen in the obstructive types.

To satisfy the purpose of our study cases were grouped as follows: 1. All those regardless of the history that presented definite or questionable histologic evidence of cirrhosis, the latter being subgrouped. 2. All cases in which the clinical history stated that the patient was addicted to alcohol. 3. Cases in which the liver weighed more than 2,000 Gm., excepting those in which the liver was enlarged as a result of leukemia, amyloid disease, carcinoma or other conditions not concerned with this study.

In the first group which showed histologic evidence of cirrhosis of various types, there were 243 cases. The incidence in the 4,000 autopsies of slightly more than

From the Medical and Pathological departments of the Philadelphia General Hospital.

Read before the Section on Gastro-Enterology and Proctology at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 13, 1936.

6 per cent Mallory¹ noted in a study of more than 8,000 autopsies covering a period of thirty-three years an incidence of 5.89 per cent. In the first table it will be noted that the majority were white males. It is significant that in this general group only eighty-four, or 35 per cent, gave a definite history of alcoholism, while in 159, or 65 per cent, there was no such history. It should be stated here that, of the 243 cases of cirrhosis, only two were observed in children.

It will be noted in table 2 that 150, or 62 per cent, of the cases, comprising the majority, as would be expected, were of the so-called portal type. We do not refer to this as alcoholic cirrhosis, which would be in agreement with most clinical classifications, as 105, or 70 per cent, of these cases did not present any history of alcoholism.

We would suggest the term degenerative instead of portal or alcoholic, as more descriptive of this type of cirrhosis. It is characterized by degeneration or necrosis of the liver cells with proliferation of fibrous tissue and bile ducts, accompanied by an extreme degree of fatty infiltration of the remainder of the liver parenchyma.

Under the fatty group we placed thirty-four cases. An extreme degree of fatty metamorphosis, which is a common finding in so-called alcoholic cirrhosis, was noted in these cases. Although it was unaccompanied by a definite bile duct proliferation or fibrosis, the picture suggested a beginning cirrhosis. Of this group, twenty-six, or 80 per cent, had an alcoholic history.

The third most frequent type was cardiac cirrhosis, of which there were thirty-three cases, or 14 per cent of the total, a sharp drop in the incidence, compared to portal cirrhosis. Twenty-eight, or 85 per cent of these thirty-three cases were nonalcoholic. We believe that a more appropriate term for this type of cirrhosis would be "circulatory." The typical histologic picture is that of so-called red atrophy, the result of prolonged failure of the circulatory system incident to advanced myocardial degeneration.

TABLE 1—History of Alcoholism

Consecutive autopsies analyzed	4 000
Total number cases of cirrhosis	243 or 6%
Alcoholic	84 (34%)
Male	66
White	57
Black	9
Female	18
White	16
Black	2
Nonalcoholic	159 (66%)
Male	87
White	63
Black	24
Female	72
White	51
Black	21

The next commonest variety was an infectious type of cirrhosis, of which there were eighteen instances, or 7 per cent. These cases exhibited in the periportal spaces increased fibrous tissue sparsely or densely infiltrated with lymphocytes and plasmocytes in particular. Bile duct proliferation was not so marked in this group. The picture strongly suggested an infectious etiology.

Biliary cirrhosis was observed in only eight cases, or 3 per cent of the total, and these were equally divided among the alcoholic and the nonalcoholic.

It is of interest to note that no case of pigment cirrhosis was observed in the 4,000 autopsies. While

hemosiderin was seen not infrequently in the sections, it was not in sufficient amounts to be of significance and we do not believe that such cases justly can be regarded as pigment cirrhosis. The true type of pigment cirrhosis, hemochromatosis, likewise was not observed, indicating its comparative rarity.

It is apparent in table 3, from a study of the age distribution in the cases studied, that cirrhosis in its fully developed form is a disease of advanced years, the largest number of cases having been observed in the sixth and seventh decades. A striking number for the age were seen in individuals between 20 and 50

TABLE 2—Ratio of Alcoholism to Types of Cirrhosis (243 Cases)

Type	Alcoholic	Nonalcoholic	Total	Per Cent
Portal Degenerative	45	105	150	62
Fatty metamorphosis	28	8	34	14
Cardiac (circulatory)	5	28	33	14
Infectious	4	14	18	7
Biliary (obstructive)	4	4	8	3
	84	159	243	

years of age. It is significant that the majority of these individuals were young white men addicted to alcohol, which is the reverse of what was encountered in the older decades. It may be that the incidence of cirrhosis in the alcoholic declines in the older age groups because such individuals do not live long enough to develop cirrhosis.

In order to establish further the relation of alcohol to cirrhosis, we selected from the 4,000 autopsies reviewed all cases in which alcoholism was mentioned in the history, as shown in table 4, of these there were 228 instances. Of these fifty-eight, or 24 per cent, showed definite cirrhosis. If we included in this group the twenty-six fatty cases showing an intense fatty infiltration or metamorphosis which is usually suspected to result from alcohol, there still would be an incidence of only 37 per cent in the alcoholic group. On the other hand, there were 144, or 63 per cent of the alcoholic group, without any evidence whatever of cirrhosis.

Still further to determine the role played by alcohol, we selected the third group, or those in which the liver weighed over 2,000 Gm, with the exceptions previously mentioned, as large, fatty livers, obviously not the result of some terminal infection, are frequently referred to as alcoholic. Of these there were 151 cases, seventy-five of which were alcoholic and seventy-six nonalcoholic. Of the alcoholic, twenty-seven, or 40 per cent, had portal cirrhosis. Eight additional cases were fatty. Of the nonalcoholic, twenty-seven or 39 per cent, had portal cirrhosis, with six additional cases fatty.

Ascites is regarded as a fairly frequent complication of cirrhosis, especially of the portal type. It was observed in our series in 35 per cent of portal, in 36 per cent of cardiac and in 50 per cent of the biliary group of cirrhoses. In the portal and cardiac types it was seen largely in the nonalcoholic, while in the biliary group it was evenly divided.

Jaundice was noted in 30 per cent of the portal, 18 per cent of the cardiac and 62 per cent of the biliary group. In the cases of portal cirrhosis, jaundice was noted in an equal number of the alcoholic and the non-alcoholic. In the cardiac and biliary cases it was observed more frequently in the nonalcoholic.

Ascites and jaundice were associated in 17 per cent of the portal, in 6 per cent of the cardiac and in 37 per

¹ Mallory F. B. *Cyclopaedia of Medicine* Philadelphia F. A. Davis Company 8 166 1935

cent of the biliary cases. Except in the biliary group, their association was slightly higher in the nonalcoholic.

Since the acute infectious diseases, such as measles, pneumonia and typhoid, are occasionally mentioned as a cause of cirrhosis, it is of interest that only seventy-six of the 243 cases of cirrhosis, or slightly more than 31 per cent, gave a history of such infections. The greater number of these were in the nonalcoholic group. It did not appear from an analysis of these cases that the acute infections played an important part in the etiology of cirrhosis.

Active pulmonary tuberculosis was found in twenty-three, or 9 per cent, of the 243 cases of cirrhosis. In eighteen of these the cirrhosis was of the portal type, ten of which were in the alcoholic and eight in the nonalcoholic. Considering therefore that 220 out of 243 cases of cirrhosis showed no evidence of active tuberculosis, it would appear that this disease is not an etiologic factor.

Syphilis was present in twenty-eight or 11 per cent, of the 243 cases of cirrhosis. It was associated with the portal type of cirrhosis in fourteen, ten of which were in the nonalcoholic and four in the alcoholic. In the remaining fourteen the cirrhosis was of varying types. Since 215 out of 243 cases of cirrhosis were observed in individuals with no evidence of syphilis, we cannot believe that this disease is of importance in the etiology.

Diabetes was associated with cirrhosis in thirteen of the 243 cases. In eight the cirrhosis was of the portal type, one being alcoholic and seven nonalcoholic. The association of these two diseases was so unusual that it did not seem to carry any significance.

The presence or absence of such gross lesions in the digestive tract as ulcer, carcinoma and gallbladder disease was noted in all the cases of cirrhosis. These

It is generally conceded that the cirrhosis attributable to alcohol is of the portal type, but it must be remembered that the same lesion occurs in children and other nonalcoholic persons as well as in certain animals. Furthermore, the incidence of cirrhosis is not in proportion to the amount of alcohol consumed in certain countries, and in some classes, such as the Hindu, who consume little if any alcohol, cirrhosis is relatively frequent.² A majority of drunkards do not have portal cirrhosis, as proved at autopsy, according to our obser-

TABLE 5—Cases (151) in Which Livers Weighed 2,000 Gr or Over

	Alcoholic	Nonalcoholic

vations and those of others.³ Finally, then, as regards the rôle of alcohol, which was the primary purpose of this analysis, it is quite evident from our observation that, contrary to prevailing opinion, alcohol cannot seriously be regarded as a specific cause of cirrhosis of the liver.

SUMMARY

From an analysis of 4,000 consecutive autopsies performed at the Philadelphia General Hospital during the period from March 1933 to July 1935 it is concluded that diabetes, syphilis, pulmonary tuberculosis and the acute infectious diseases, as well as such gross lesions in the digestive tract as ulcer, carcinoma and gallbladder disease, do not bear any relation to the incidence of cirrhosis. It is further concluded that alcohol cannot be regarded as a specific factor in the etiology of cirrhosis. As the lesion defined as portal cirrhosis occurs under influences unassociated with alcohol we would suggest abandonment of the term "alcoholic cirrhosis."

Rittenhouse Plaza

ABSTRACT OF DISCUSSION

DR. LEONARD G. ROWNTREE, Philadelphia: I have been interested in this study of Drs. Boles and Clark, particularly in their suggestion as to reclassification of liver disease. In all forms of chronic disease, many attempts are passed through before final classification is attained. Classification eventually leads to clarity. Relative to the rôle of alcohol in the pathogenesis of cirrhosis of the liver I will discuss three groups of statistics. The first gives the incidence of both diseases from 1910 to 1932 inclusive, as revealed in the mortality statistics for the registration area of the United States. It is apparent that with the advent of prohibition the incidence of cirrhosis of the liver in this country dropped 50 per cent. The patients studied in the authors' series came at a period immediately before and after the repeal of the Eighteenth Amendment. It represents, therefore, a transition period. The second group contrasts the incidence of liver cirrhosis and alcoholism in urban and rural districts. New York State is essentially urban and Kansas rural and in addition Kansas had state prohibition prior to 1917. In New York State the incidence of cirrhosis following prohibition dropped to about one third of its former level whereas in Kansas the incidence of both alcoholism and cirrhosis is relatively unaffected. In the Co-

TABLE 3—Age Distribution in Cirrhosis (243 Cases)

	Alcoholic	Nonalcoholic	Total
0-9	0	2	2
10-19	0	2	2
20-29	6	4	10
30-39	16	11	27
40-49	20	18	38
50-59	16	40	56
60-69	18	47	65
70-79	8	29	37
80-89	0	6	6
Totals	84	159	243

TABLE 4—Condition Found in Cases of Alcoholism

	Total cases of alcoholism	
Definite cirrhosis	58	24%
Fatty metamorphosis	26	13%
No cirrhosis	144	63%

lesions occurred so infrequently that it was quite obvious that they bore no relation to the condition.

From the foregoing analysis it would appear very doubtful that diabetes, syphilis, tuberculosis, the acute infectious diseases or common gross lesions in the digestive tract are of importance in the etiology of cirrhosis. Whatever their influence might be it is greater in the nonalcoholic group. It is interesting to note in this connection that the ratio of these conditions in the nonalcoholic to the alcoholic is almost 2:1 which is approximately the same ratio of alcoholism observed in the total number of cirrhoses.

² Rolleston, Humphry and McVee. J. W. Dis. of the Liver, Gall Bladder and Bile Ducts, ed. J. London: Macmillan Co., 1934, p. 216. ³ Tirumurti, T. S., and Radhakrishna Rao. M. A. J. Ind. Med. Assoc. 69: 7476 (Feb.) 1934. Radhakrishna Rao. M. A. J. Ind. Med. Assoc. 21: 349-416 (Oct.) 1933. ⁴ Formad, H. F. Tr. A. Am. Physicians 1: 225 (1935).

County Hospital, following prohibition, the incidence dropped from 600 a year to from 100 to 200 annually. In Montreal, in what might be considered a favorite "wet area" during prohibition, the incidence of cirrhosis increased. In the Mayo Clinic the incidence of cirrhosis is relatively unaffected by prohibition. The question discussed by the authors is one of paramount importance. A study from the Philadelphia Hospital comparable in character, but covering a period from 1920 to 1923, might reveal contrasts of considerable interest. In all studies involving alcoholism and cirrhosis of the liver there should be sounded one word of caution, i. e., the patient's word is not always trustworthy, and hence other forms of evidence, if available, are desirable. Judging from the statistics available, alcohol in this country is responsible for approximately 50 per cent of the cases of cirrhosis of the liver.

DR. HENRY L. BOCKUS Philadelphia. In 1685 Browne stated that hardening of the liver in association with ascites was probably due to the drinking of too much water. Paine stated in 1889 that this was a "fault which the bold spirits of the time were much on their guard against." In 1793 Bailie mentioned alcoholism as a factor in the production of cirrhosis and since that time it has come down to us. Chronic fibrosis of the liver must depend on many factors on where one lives and how. In the Fijian Islands cirrhosis is attributed to a mytilotoxin from mussels and in Egypt to bilharziasis. The excessive ingestion of spices, such as ginger and cardamom may account for cirrhosis among the nonalcoholic Hindus. Among coal miners it has been attributed to anthracosis and among stone masons to silicosis. Arsenic, manganese, copper, aluminum, chloroform, naphthol and phosphorus have all been mentioned as possible causes. Many feel that the amount of the toxin and rapidity with which it acts determine the character of liver damage—whether a massive hepatocellular change or a chronic fibrosing inflammation. The authors have mentioned that gastroduodenitis may be a primary factor aided and abetted by alcohol. Mallory has described cases of cirrhosis attributed to a streptococcus and to a colon bacillus. Syphilis and primary splenomegalic disorders such as Banti's disease, Gaucher's disease and chronic malaria, must account for some cases. Mention should be made also of conditions predisposing to liver injury as lowering of the glycogen reserve due to dietary deficiency or increased metabolism as well as to anoxemia. The authors have mentioned a new classification for cirrhosis: circulatory, degenerative, infectious and obstructive. Possibly this might be further reduced to three types by combining the degenerative and infectious in one group under the term toxic-infectious. The classification would then be an etiologic one: (1) circulatory, (2) toxic-infectious, (3) obstructive. The latter concept of cirrhosis favors clear thinking in that it discourages the consideration of cirrhotics as a distinct clinical and pathologic entity dependent on any one cause. Physicians should be on the alert for the many etiologic factors that may be responsible for hepatic fibrosis.

DR. RUSSELL S. BOLES Philadelphia. I certainly do not want to give any impression of condoning the use of alcohol. I should like to know whether Dr. Rowntree's statistics were vital statistics, based on clinical diagnoses. I would draw attention to the fact that our conclusions were reached solely on the basis of histologic evidence. We are not trying to draw conclusions as to etiology or trying to explain our observations in any way. We simply present what we have found. If Dr. Rowntree's curves are plotted on a basis of vital statistics in turn based on clinical diagnoses throughout the country at large I think they are open to a question as to their accuracy. It is surprising how frequently the clinical diagnosis of portal cirrhosis is wrong. It is an easy clinical diagnosis to make, but is often a difficult pathologic diagnosis to prove when it has been made clinically. The clientele of some clinics is of course, quite different from that which we get at old Blockley. When they say there that they drink, they mean a quart or 2 or 3 quarts a day. Furthermore drunkards are notoriously inaccurate when they say they drink but little. If alcohol is a factor in producing cirrhosis, a greater incidence during the years of prohibition ought to be found because, if cirrhosis is produced by alcohol, it probably takes a number of years to bring it about, and therefore the drinking that was done prior to pro-

hibition would obviously show its effects during prohibition and result in a higher incidence. Dr. Bockus's remarks are interesting and well taken. We separate the infectious type from the degenerative because histologically they each present a characteristic picture. I trust that our conclusions will not carry assurance to any one that he is less likely to get cirrhosis if he does drink than if he doesn't drink. From our analysis of the age incidence, it would appear rather conclusive that if drinking has anything to do with cirrhosis it is the drinking done in the more tender years that carries the greater hazard than that done in later years.

LUPUS ERYTHEMATOSUS

A MODIFICATION OF THERAPY WITH GOLD COMPOUNDS

HERBERT S. ALDEN, M.D.

AND

JACK W. JONES, M.D.

ATLANTA, GA.

The alchemists dreamed of a "pure essence of gold" hidden under its divers veils of dross and by a leap of logic hard for present-day minds to follow, reasoned that, if large doses of this dross free element were consumed, all man's ills would be purged away. Curiously enough eight centuries later the medical profession finds itself hovering closely on the edge of the same dream. Moellgaard¹ dreamed of patients rid of pulmonary tuberculosis by a few injections of gold into the circulating blood. Many others saw and dreamed of a spectacular cure of lupus. And now it is in some quarters used enthusiastically for arthritis and asthma.²

While it is well established that certain gold salts may be given intravenously in lupus erythematosus, sometimes with spectacular success, the profession must remain acutely conscious that such treatment has many limitations and is often attended with much danger. The repeatedly reported clinical "cures" and symptomatic relief are clearly supported by the experience of many of us, but there is in the air evidence of an enthusiasm too early divorced from caution. One has but to pass an eye down the column headed "gold" in the *Quarterly Cumulative Index Medicus* to note the frequent occurrence of serious accidents following its use as well as the multitude of disorders for which its use is recommended.

The use of gold salts in pulmonary tuberculosis came about originally as the result of Koch's discovery that gold produced a bactericidal action on the tubercle bacillus in vitro. Moellgaard¹ believed that it prevented experimental tuberculosis in rabbits and calves and would cure pulmonary tuberculosis in man. But when it was used in man it was often followed by disastrous results. These disastrous results were attributed to the death and liberation of large numbers of tubercle bacilli but are now known to be the result of the death of tissue from the gold salts. Large doses were given in an effort to produce a theoretical sterilization which in fact did not exist. In spite of disasters, however, many still hold that the gold salts possess much useful-

From the Department of Dermatology, Emory University School of Medicine.

ness in certain forms of pulmonary tuberculosis but its specificity for the tubercle bacillus is no longer held.³

It was a short jump from the use of gold in pulmonary tuberculosis to its use in tuberculosis of the skin and thence to lupus erythematosus, on the mistaken notion of its tuberculous etiology, and so its dermatologic usefulness has roughly paralleled its history with pulmonary tuberculosis. It is now more or less generally believed that the gold compounds cause stimulation of all cells entering into the formation of chronic inflammation and into the process of healing,³ hence there is some reason for its apparent value in chronic arthritis and asthma.

All reports agree on the toxicity of the gold compounds.⁴ Experimental work shows that gold even in high dilutions, like arsenic, is a capillary poison, seemingly having a selective action on the contractile elements of the vessel wall. Following the intravenous injection in the experimental animal there is a sudden dilatation of capillaries, the capillary bed being increased fourfold, hemorrhage and slowing of the blood stream occur, and the animal is "bled" to death in its own capillaries. When gold is given more slowly, in smaller or more dilute doses, capillary reaction also occurs, but much of the element is retained and distributed in the connective tissue bed surrounding the capillaries notably in connection with the histiocytes, and there it can be demonstrated by spectrometric tests.⁶ Some of the elementary gold apparently escapes with the histiocytes through the mucous membranes of the lung, the gastrointestinal tract and the kidneys. It therefore may be readily seen how a sudden suffusion of the body with large doses of gold may lead to severe and even fatal results. One may also read in such observations a theoretical explanation for the action of gold in a chronic inflammation such as lupus erythematosus.

All reports likewise agree on the value of gold in the alleviation of lupus erythematosus, the earlier reports showing relatively much more enthusiasm.⁴ The more recent observations seem to be in favor of extreme care in reporting complete cures. We have all observed clinically the rapid dissolution of inflammation and edema in a small patch of relatively early lupus erythematosus after a few injections of gold as often as we have observed the slow reaction to such treatment in the old and scarred lesion. Experimentally, gold produces varying degrees of inflammatory reaction, depending on its concentration and location, and factors such

as capillary dilatation, inflammation or injury to tissue seem to favor its deposition in larger quantities.⁶ It would seem that there is at hand a drug which may produce a varying degree of counterirritation in some what the same manner as the application of heat, except that it is more continuous in its action—but with heat one can readily and immediately remove the counter irritant, whereas with gold the remedy is often irrevocable.

Driver and Weller⁷ and recently Wright⁸ have quite clearly demonstrated a high percentage of accidents following the use of gold compounds, the latter reporting a 25 per cent reaction in all cases that he had treated intravenously. The reactions observed by others have been as a whole in excess of this. Cole⁹ went so far as to doubt whether the values of gold compounds outweighed their dangers. While undoubtedly the fatalities and reactions reported may be in part due to overdosage, injudicious use or individual sensitivity, the gold salts are nevertheless often administered by those uninformed of their dangers. It would seem wise therefore, to consider favorably a useful method of giving gold which is as near fool proof as possible, yet containing much of its efficacious qualities. Both the manufacturers of gold compounds and the clinicians using these preparations have attempted to devise formulas that will prevent accidents—witness the long list of gold compounds in use today. Monash and Traub¹⁰ have suggested that the gold compounds should be given intracutaneously directly into the diseased tissue—a method somewhat uncomfortable but provocative of good results. Traub¹¹ later reports that the same result may be obtained with other metallic substances.

The majority of the gold compounds in use have been marketed in the form of a crystalline powder with instructions to give immediately after they have been dissolved in distilled water thus preventing reaction due to oxidation of the solution. In recent years an American manufacturer has marketed gold and sodium thiosulfate, $\text{Na}_2\text{Au}(\text{S}_2\text{O}_3)_2 \cdot 2\text{H}_2\text{O}$, in a stable buffered aqueous solution instead of as a crystalline powder. Such a solution ready for immediate use eliminates many possible chances of error, such as contamination use of poorly distilled water, and the occurrence of oxidation products. In a small clinic or in the office where time and assistance may be at a premium, such a preparation is of considerable value.

Since the fall of 1931 we have treated fifteen patients having lupus erythematosus with this prepared stable solution of gold and sodium thiosulfate, given hypodermically instead of intravenously as usually given.¹ Twelve of these cases we have been able to follow and determine the results of treatment. Four of the twelve we can record as arrested at the present writing. We use the term "arrested" rather than "cure," since our experience with the use of gold salts in lupus erythematosus has been that the determination of "cures" is difficult if not doubtful. All these patients have improved while undergoing treatment. With the exception of one, all the patients had one or more recurrences in areas apparently healed or in new areas. In only

one instance can we record any evidence of reaction to the drug given subcutaneously and that, focal in character, was in a patient known to be sensitive to gold preparations. Previous to the use of this method we had treated three cases of lupus erythematosus by the intravenous route with triphal (sodium salt of aurothiobenzenedazole-carboxylic acid) and one with gold and sodium thiosulfate. In two of these cases general reactions developed, one severely with dissemination of the disease, so we had a healthy respect for the dangers of gold salts intravenously and welcomed this innovation.

The drug at first was marketed in ampules containing 25 mg of gold and sodium thiosulfate dissolved in 2.5 cc of water. The contents of the ampule were given subcutaneously in the upper arm at intervals of one week. Any larger quantity of solution seemed to produce considerable pain. Owing to an increase in the number of patients applying for treatment and the limited supply of the drug, we later had to reduce the weekly dosage to 12.5 mg and found that the results in most instances were just about as good. The improvement in the eruption was not as rapid as in some instances in which gold was given intravenously,

Summary of Twelve Cases Treated with Gold and Sodium Thiosulfate

Case	Age	Sex	Color	Duration of Eruption	Type of Eruption	Type of Treatment	Total Mg Gold	Comment
1	36	F	Negro	4 yrs progressive	Flat wlog chronic discoid	Gold and sodium thiosulfate subcutaneously once weekly	670	Improved slowly under both types of treatment after one year had slight recurrence stopped treatment
2	20	F	Negro	1 yr	Cheeks discoid	Gold and sodium thiosulfate subcutaneously once weekly	975	After 16 injections 20 mg each clear recurrence 1 mo 19 injections 20 mg each clear followed by second recurrence stopped treatment
3	11	F	Negro	1½ yrs	Cheeks nose tips of fingers discoid	Gold and sodium thiosulfate	920	Fingers clear after 17 injections 20 mg each face improved after 15 injections recurrence after 1 yr rest 9 more injections little improvement stopped treatment
4	24	F	Negro	6 mos	Tip of nose, upper lip discoid	Gold and sodium thiosulfate subcutaneously	500	After 8 injections 25 mg each clear recurrence upper lip in 5 mos 11 injections improvement after 8 injections triweekly 10 mg each marked improvement
5	12	F	White	1 yr	Tip of nose discoid	Gold and sodium thiosulfate weekly and triweekly	600	Well after 9 injections 20 mg each recurrence 8 mos 10 mg every other day
6	40	F	White	4 mos	Cheeks and tip of nose discoid	Gold and sodium thiosulfate tri weekly	170	Continued improvement regular treatment 17 injections well
7	40	M	White	3½ yrs	Cheeks discoid	Gold and sodium thiosulfate bi weekly	170	Treatment regular biweekly marked improvement pulmonary tuberculosis healed
8	42	F	White	5 yrs	Recurrent to summer, disseminated erythematous areas legs feet body	Gold and sodium thiosulfate tri weekly	200	Treatment continued improvement acute return followed x-ray treatment of ulcer quickly subsided Well tuberculous ulcer surgically removed
9	27	F	White	6 mos	Discoid type temple	Triphal intravenously gold and sodium thiosulfate subcutaneously weekly triweekly and daily	2600	Improved much on triphal intravenously 1929 remained so 2 yrs after 20 injections gold and sodium thiosulfate 20 mg each intravenously and 31 subcutaneously improved 3 years later recurrence upper lip 16 subcutaneous injections weekly 10 mg improvement under treatment weekly injections 10 mg each subcutaneously improved
10	60	M	White	6 mos	Superficial erythematous type ears and cheeks	Gold and sodium thiosulfate subcutaneously weekly	1600	Improved gradually over period of 1½ yrs fairly regular treatment at present 14 clear of trouble
11	40	M	White	20 yrs	Diffuse discoid type	Gold and sodium thiosulfate intravenously and subcutaneously	?	Unimproved under intravenous treatment and had reaction no improvement subcutaneous injections gold and had mild focal reaction
12	14	F	Negro	6 yrs	Small discoid base of nose	Gold and sodium thiosulfate subcutaneously once weekly	372	Thirteen regular weekly injections well recurrence 2 mos later 3 injections well remained so for 1½ yrs

METHOD OF TREATMENT

The method of giving gold and sodium thiosulfate subcutaneously came about purely by accident and by the fortuitous collusion of circumstances. In a small dermatologic clinic, lack of time and assistance made it difficult to dissolve the gold salts and give them intravenously. After we had obtained a small quantity of the aqueous solution of gold and sodium thiosulfate from the manufacturers we administered several doses by the intracutaneous method advocated by Monash and Traub.¹⁰ On observation that there was considerable improvement in the areas of lupus erythematosus that were not treated a single subcutaneous injection was given in the upper arm, with surprisingly little pain and discomfort and after several doses with much improvement. It was obvious that if this method could be used treatment would be much simplified and could be given with ease by a nurse or untrained assistant

but it had its compensations in safety and simplicity. After two years of experience in six cases of lupus erythematosus we had observed no local or general reactions with this method and no induration, pain or discoloration at the site of injection and we began to give doses of 10 mg (1 cc of solution) subcutaneously every other day and in some instances daily. This method brought about a more rapid improvement in the disease in most instances so much so that two patients asked specifically for more frequent doses. This manner of treatment was facilitated by the marketing of the gold solution in rubber-stoppered ampules containing 5 cc of solution (50 mg) from which small quantities might be taken without fear of contamination of the remaining stock. Our best results have been obtained in those patients who were able to get 10 mg of gold and sodium thiosulfate subcutaneously regularly three times a week.

Of the twelve cases that we were able to follow and observe, five occurred in Negroes, curiously all women. The disease in all instances was of the chronic, slowly progressive, discoid type, leaving much destruction in its wake (enhanced by the tendency toward depigmentation). As a whole the results of treatment in the Negro were neither as rapid nor as satisfactory as in the white patients, owing much to their disinterest and irregularity and frequent discontinuance of treatment, so we can record but one arrested case among them.

We were able to follow up more or less accurately all twelve of our cases, as shown in the accompanying table. Four of these cases, 33⅓ per cent, can be considered at the present writing as arrested. Six patients, or 50 per cent, have had a marked improvement in their eruption, and in two the eruption has remained stationary after an initial improvement. All but two of the patients had at some time a recurrence of the disease either at the original site or in a new area. Two of the cases occurred in children, both of whom tolerated the drug well and improved quite rapidly, but recurrences were frequent. One of our cases was of the superficial disseminate type, in which acute dissemination had occurred following exposure to sunlight. The patient had no untoward reaction to gold treatment but did have a twenty-four hour flare up following roentgen irradiation to a tuberculous ulcer. The eruption has been arrested for some months. In no instance could we consider this method of treatment as provocative of any general reaction, and in only one instance was there any focal reaction and that in an individual known to be sensitive to gold preparations.

REPORT OF CASES

CASE 6—A white American housewife, aged 45, asked for relief of an atrophic erythematous eruption the size of a quarter dollar (24 mm) on each side of the bridge of the nose extending to the lower lids, and a single small patch on the tip of the nose. All areas had been spreading since their appearance four months before. A diagnosis of lupus erythematosus was made and she was given 10 mg (1 cc of solution) of gold and sodium thiosulfate subcutaneously every other day for thirteen successive doses. After the third injection there was slight itching of the affected areas. After the fifth injection, marked improvement was noted. After the thirteenth injection the original lesions were hardly apparent. She was then given four additional injections at weekly intervals. Her skin has remained clear for six months. Total treatment lasted two months and she received a total of 170 mg of gold and sodium thiosulfate.

This case exhibited a rather marked and rapid improvement. Much of this improvement must be ascribed to early diagnosis and to regularity and frequency of treatment.

CASE 3—A Negro school girl, aged 11 years, came for relief of a slowly spreading scarring eruption on the cheeks, nose and tips of the fingers, which had been present for eighteen months. A diagnosis of lupus erythematosus was made and she was given 25 mg of gold and sodium thiosulfate (25 cc. of solution) subcutaneously in the upper arm at irregular weekly intervals. After thirteen injections the eruption on the fingers had cleared and the areas on the face had partially improved. Fifteen more injections at more irregular intervals resulted in slight improvement in the face. She returned one year after the last injection with a definite increase in the area of eruption on the face but no recurrence on the fingers and she received nine more injections with little or no improvement, and she stopped treatment.

The patient refused to take treatments three times a week, and even all attempts to get her to take regular

weekly treatments failed. This fact and the length of time she had the eruption account to some extent for her lack of improvement.

CASE 9—A white American housewife, aged 27, asked for relief of an atrophic erythematous skin eruption the size of a ten-cent piece (18 mm) on the right temple. She was given a number of intravenous injections of triphal, 50 mg each at weekly intervals (number unknown), with complete healing of the lesion. One year later a recurrence of the superficial erythematous type occurred on both temples and under the left eye and cheek. Eight injections of gold and sodium thiosulfate intravenously in 25 and 100 mg doses resulted in relief. Two years later she returned with a discoid infiltrative type of eruption on the temples and cheeks which had been present for eighteen months and slowly spreading. She was given four intravenous doses of gold and sodium thiosulfate, 100 mg each, and she stopped treatment for two years, at which time the lesion had spread and become scarred and infiltrated. She was then started on gold and sodium thiosulfate subcutaneously in 25 mg doses at weekly intervals. After thirteen doses there was very little spread and at the patient's request the injections were given intravenously. After fourteen weekly injections still no improvement was noted. Gold and sodium thiosulfate was then begun subcutaneously three times a week. She is still under treatment with very slight improvement.

This case illustrates the often observed good effect of gold preparations in the early erythematous type of lupus erythematosus. The almost complete lack of improvement under gold therapy in the recurring lesion is difficult to explain.

COMMENT

Doubtless all will agree that in the treatment of this disease the safety of the patient is of paramount importance. Particularly is this true in the dermatologic manifestations of disease, such as lupus erythematosus which rarely produce death. In contemplating the treatment of such a disease, with a drug which is known to produce reactions, sometimes of a severe degree and occasionally death, one must weigh carefully the risks to be taken. If under the best care at least 25 per cent of cases treated result in reactions and one third are arrested or "cured" and one half are improved, the margin of profit in treatment does not seem to be great. But such is the situation after ten years of experience with the treatment of lupus erythematosus with gold compounds.¹³ However, when one considers how unproductive of results other therapeutic endeavors have been in the past, such results are, to say the least, gratifying. Since the more general use of gold compounds in lupus erythematosus the quantitative dose recommended has steadily lessened, and more and more one reads statements of relief of symptoms on dosages so small as to be hardly considered by earlier workers.¹⁴ As the heat of enthusiasm calms it must be realized that one cannot expect quite the curative results that were reported in the beginning, unless one is willing to sacrifice lives and health, and it must also be realized that the gold compounds are not specific for lupus erythematosus. As much as we would like to share Semon's¹⁵ prophecy and hope of 1927 that the gold compound will in the future be as specific and efficacious in lupus erythematosus as arsenic is in syphilis, we find it impossible to do so.

In all the cases herein reported we have throughout given amounts of gold that are relatively small in the

light of previous reports, with results not as spectacular but comparable. We have used a prepared stable aqueous solution of gold and sodium thiosulfate which is simple in application and is given subcutaneously rather than intravenously and hence is less likely to result in accidents either from the method or from biologic phenomena. Taken as a whole the injection of gold and sodium thiosulfate subcutaneously in our cases has been free from fear of untoward reactions and simple in application and not uncomfortable to the patient, as well as efficacious in the relief of symptoms of lupus erythematosus. We believe that, all things considered, this method of giving gold salts to patients with lupus erythematosus is probably safer, more fool proof, simpler and probably as efficacious as the intravenous route.

711 Medical Arts Building

ABSTRACT OF DISCUSSION

DR. JAMES K. HOWLES, New Orleans. While my experience has not been that of the authors in some thirty-odd cases which have been treated at Charity Hospital we have noticed no untoward results, no general reactions. I have, however, as high a regard for the symptoms of pruritus in the treatment of intravenous gold preparations as I have for intravenous arsenicals. Perhaps much of the adverse criticism is due to the fact that proper preparation is not achieved or selection of cases is not practiced. The champions of other therapeutic agents in lupus erythematosus report results just as favorable and promising as those of the gold therapists. Bismuth, both the subsalicylate and other forms, bismuth oxychloride, the arsenicals in the pentavalent form, acetarsone and even tuberculin have had their proponents, so that the possibility of the nonspecific effect of this drug must not be disregarded. It is granted by all that it is not a specific drug and that the action is thought to be on the inflammatory process and the healing process, in fact on all the cells that take part in those processes. If such is the case, perhaps a combination of drugs might obtain the desired result. I wonder whether a combination of gold preparations with bismuth wouldn't obtain results more favorable than the individual drugs. Intramuscular or subcutaneous medication is safer than intravenous. The subcutaneous method is far more desirable, especially for general practitioners. Perhaps sensitization enters into the question, it may be possible in time to do skin tests to eliminate individuals sensitive to gold. I have often noticed in patients treated with intravenous gold preparations a complaint of pruritus immediately afterward and sometimes a slightly delayed reaction. In thirty cases I have never noted any severe reaction.

DR. M. E. OBERMAYER, Chicago. Drs. Alden and Jones have emphasized in their work the safety of this new method. It was with the same view in mind that we undertook at the University of Chicago in 1931 the clinical study of a new gold compound which was synthesized by Kharasch and Isbell of our Department of Chemistry. This compound is ammonium succinimide aurate, $\text{NH}_4\text{Au}(\text{C}_4\text{H}_4\text{O}_2\text{N})_2 \cdot 4\text{H}_2\text{O}$. Its toxicity is so low that 1 Gm. of the substance caused no toxic phenomena in a rabbit of 3 Kg. We have been using this compound for the last five years with satisfactory results. The therapeutic effect of ammonium succinimide aurate was found to be somewhat equal to that of gold and sodium thiosulfate, but it is in the paucity and mildness of the reactions that the new compound shows its superiority. Gold dermatitis for instance, was completely absent. In spite of single doses as high as 1,000 mg., the toxic reactions that have been observed so far were practically negligible. We feel that like Dr. Alden and Dr. Jones, we have contributed to the safety of gold therapy and a report on these studies will be made in the near future.

DR. MARTIN ENGMAN JR., St. Louis. I would like to relate an incident that occurred in my father's ward when gold first came out. He had treated a few cases and had good results. One day there came to the ward at Barnes a patient with an acute disseminated lupus erythematosus. Gold was ordered intravenously, the dosage being stated to the intern. The next morning the patient was at least 50 per cent better and my

father remarked to the students and interns what a wonderful acquisition gold was in the treatment of the disease. Meantime the intern was pulling at his sleeve, trying to get a word in. "But Doctor, by some mistake the patient didn't get the gold that you prescribed." I don't know whether we are right or not, but we look at the leukocyte count as a rough guide and the type of lupus erythematosus as a guide in the administration of gold. If the leukocyte count is lower than 5,000, we decide that gold therapy should be delayed until the leukocyte count is brought up. We are not quite sure just why we do this, but we base it mainly on the fact that there is definitely a lowered leukocyte count in disseminated cases. We don't like to give gold in disseminated cases that are very acute or are becoming acute.

DR. JOHN HOWARD KING, Nashville, Tenn. About ten years ago the use of gold salts in this country created enthusiasm. Indiscriminate and indiscreet practice followed. During the past three years there has been much criticism of these drugs, tending to deprive physicians of their most valuable weapon in combating this disease. Recently I reviewed some work of Dr. Hamilton and myself. It covers a period of ten years. During that time we treated ninety-six cases of lupus erythematosus with sodium gold thiosulfate. We had no deaths. There were six obvious reactions. Only one was severe enough to put the patient to bed. This was an elderly woman with a distinct nephritis. The other five reactions were in ambulatory and casual patients. One patient had mild exfoliative dermatitis. The earliest sign was stomatitis, especially seen on the inner surface of the lower lip. That was our danger sign. Two unusual reactions were observed. The patients had malaise and soreness in the sides of the neck, a sort of cervical adenitis lasting three or four days. In the severe cases recovery occurred in three weeks. Between 1,100 and 1,200 doses were given intravenously. They varied from 10 to 100 mg. The majority were 100 mg. All but twelve patients were private patients closely observed. Various reports show from 20 to 30 per cent reactions. Several deaths are reported. Our percentage of reactions is about six, with no deaths. About 80 per cent of the cases were well arrested. About 30 per cent relapsed and were rearrested. A small percentage were arrested the third time. I congratulate the authors on the presentation. It may prove to be a valuable contribution in preventing the discontinuance of this most valuable drug.

DR. WILEY M. SAMS, Miami, Fla. I should like to comment on Dr. Engman's remarks regarding the importance of leukopenia. I have had one serious reaction in a small number of cases treated. This reaction occurred after the woman had had a good number of injections without any reaction whatever. She had had no gold given for about three weeks, but during that time she had had dengue fever, a disease which is characterized by leukopenia. The next injection produced a fulminating exacerbation.

DR. HERBERT RATTNER, Chicago. I should like to report briefly our experience at the University of Illinois. After Dr. Jones's preliminary report of this method of treatment we undertook it in some fifteen or twenty cases. We gave smaller doses, we didn't give them as often as the present report states but we soon discontinued the treatment because we felt definitely that results were not as good as with the intravenous method, and in almost every case we found it necessary to discontinue the subcutaneous method and go back to the intravenous. It is true that there was no pain and none of the reactions that are sometimes encountered when gold compounds are administered intravenously.

DR. HERBERT S. ALDEN, Atlanta, Ga. I had no intention of presenting too severe a picture of gold reaction, it was merely the picture that I get from the literature. It seemed to us that although the method was not as spectacular and not quite as immediately efficacious as the intravenous method, it would be the best method that could be used in a general way, particularly among the general practitioners. It is a method that one could prescribe for the general practitioner in the smaller towns surrounding one's community and ask him to give over a longer period of time without fear that the patient would get into difficulties. It was more with that in view that we reported these results, in an effort to give the country patient the opportunity to get gold by a safer method. In regard to Dr. King's remarks as to why he didn't get gold reactions, I have no

answer I don't think any one knows just why people have reactions to gold. We are glad to hear of Dr. Obermayer's gold preparation, ammonium succinimide aurate. It should prove to be of great value. I think one will find that if one uses the subcutaneous method of administering gold in the office or the clinic one will feel that it is not as spectacular, but for some of us who have small dermatologic clinics and treat referred patients coming from the outlying districts I am sure it will be of distinct value.

TERMINATION OF ONE THOUSAND ATTACKS OF MIGRAINE WITH ERGOTAMINE TARTRATE

MARY E. O'SULLIVAN, M.D.

NEW YORK

For the past few years in the neurologic service at Bellevue Hospital, under the direction of Dr. Foster Kennedy we have been studying the etiology and treatment of migraine. Realizing that this affliction is not a disease entity and that there is more than one precipitating factor in the production of this syndrome, we felt it essential to investigate this paradox from many different angles.

In a report in 1934 we¹ approached the problem from a pharmacologic point of view. At that time we administered known vasodilator and vasoconstrictor agents, also glandular products such as pitressin, extract of anterior pituitary, theelin and insulin. We also studied the effects of carbon dioxide inhalation, of vagomimetic and of sympathomimetic compounds on the attacks. These various medications were used in order to compare the relative effectiveness of numerous nonsedative measures in relieving the episode, as well as to determine the factors capable of precipitating a headache.

The diversity of our results during these investigations reinforced our belief that the pathophysiology in the production of migraine is not a single one. We did not prove its mechanism. Our results in appraising the nonsedative medicines used to relieve the attacks were more explicit.

Eleven medications were administered during the migraine headache in order to effect relief. They were caffeine, histamine, epinephrine, ephedrine, mechlorin, amniotin, tissue extract, pitressin, amyl nitrate, calcium gluconate intravenously and ergotamine tartrate. Of these, ergotamine tartrate was the only drug that gave definite and constant results. Its effect was outstanding. The other medications might help on the first injection but fail at another time to benefit the very same person. These other measures might relieve two patients and then fail in seven others. The relief obtained from ergotamine tartrate was dramatic. It completely checked thirty-four headaches in fourteen patients. It failed to alleviate only five headaches in four patients. We noticed that, once it relieved an episode, control of future attacks in that individual was assured if the drug was given in adequate dosage.

In discussing the value of a medication in the treatment of as complex a syndrome as migraine a group of eighteen patients is not a sufficient number from which to draw any worthwhile conclusions. Because of this and because of the consistent and spectacular

relief obtained from the drug, we felt that further study of its action in relieving the attack should be undertaken.

Our criteria for diagnosis and inclusion in our migraine research series have been discussed in a previous report.¹ These patients have received metabolic studies and blood chemistry and Wassermann tests. X-ray plates of the skull, the sella turcica and the nasal accessory sinuses were taken, and also a gastro-intestinal and a gallbladder series if indicated by the anamnesis. The patients were thoroughly examined for any pathologic process that might be active in the various bodily systems, since they were examined by a psychiatrist, an allergist, a rhinologist and an ophthalmologist.

CHECKING OF ATTACKS BY SUBCUTANEOUS INJECTION

We have now used ergotamine tartrate over a two year period and can discuss our results after having administered the drug for the relief of 1,132 headaches. There were ninety-seven patients—seventy-eight females and nineteen males—in this later study. Their ages varied from 11 to 51 years. They had suffered from migraine for from six months to forty-eight years, the average duration of the illness was sixteen years, the frequency of the attacks varied from two a week to one or two a year.

All but eight of the ninety-seven patients were benefited by this medicament. It completely checked 1,042 episodes in eighty-nine persons. Of the eight patients whose headaches were not controlled by ergotamine tartrate there were four who believed that the pain was alleviated by the injection. The relief obtained was not complete, however, and "of no more benefit than a headache powder." They were not included in our larger group because its criterion is abrupt termination of the attacks.

We found that there was no difference in the action of the medicament when given to men and to women. It was administered to nineteen men and all but three of them were benefited by the alkaloid. The proportion three out of nineteen is practically the same ratio that occurs with the common use of the drug.

Early in our investigations we realized that ergotamine tartrate could not be used as a cure for migraine. It is most impracticable to dispense it as a preventive of the attacks even though it is of unquestionable value in aborting them. This ability to check the episodes unfailingly is, however, a worthy tool to use while one is searching for a cause and cure of the malady. It gives the investigator something very definite to offer the patients, without interfering with the effects of his other investigations. It bolsters the patient's spirits, many of them stating "Well, if you can't do any more for me than you have done, it will still be very wonderful."

Ergotamine tartrate has no effect on the frequency of the attacks. Several patients stated in their usual disheartened manner, that the episodes were coming more frequently since they had been receiving the injections. On examining our charts and studying the intervals of the headaches before and after the use of the drug, we noticed a shorter interval occurring in only three of our patients. Two of these, were women at the menopause, and one was a man aged 48. They had suffered from migraine "all their lives" and the interval had become shorter and shorter through the years, therefore this diminishing frequency should not necessarily be considered an effect of ergotamine tartrate. At other

times, when from our data we felt that the drug was increasing the attacks, with further study this lessened interval was found to be only temporary. Such an irregularity in the occurrence of the episodes is a very characteristic finding in migraine, whether the patients take any medication or not.

A number of these men and women have expressed the fear that the beneficial effects of this medicine would wear off. They said that all the other medications that they had ever taken would relieve the attacks for a few months but after a short time would become ineffective. Their skepticism has so far proved to be unfounded. While using ergotamine tartrate over a two year period we have never seen it fail to check an attack merely because of continued usage. One individual whose attacks have been coming weekly has received 129 injections, another patient sixty-four and a third fifty-eight, they have always had unfailing relief from this medicament.

The same infallibility holds true for all our eighty-nine patients. Once ergotamine tartrate has abolished an attack, it has never failed, in our two years' experience, to check again a migraine headache in that individual if given in adequate dosage.

DOSAGE

The amount of alkaloid required to effect relief, however, is very important in proving or disproving this infallibility theory and is worthy of a little consideration. The minimum effective dose, of course, is directly proportional to the severity of the attack. The severity of the consecutive attacks in migraine, as every one knows, is exceedingly variable. Some attacks will be particularly intense, continuing for two or three days, while others occurring in the same individual will be rather moderate and will last only a few hours. Unless one keeps this in mind the headaches may be abruptly terminated four out of five times, but the fifth attack may be one of these very severe ones, the dose may be inadequate, the effect disappointing and the patient discouraged. By anticipating this (the patients can usually tell when they are 'in for a bad one'), a slightly larger dose may be given and an unsatisfactory experience avoided.

Eight episodes, which would have continued for from three to five days if they had not been checked by the alkaloid in from one to three hours, returned from twelve to twenty-four hours after the injection in eight of our cases. This recurrence of the headaches is the exception and not the rule, however, for the same eight persons have obtained complete and permanent relief from sixty-two other attacks. We believe that this reappearance is again probably the result of inadequate dosage. A second injection will control this returned episode.

While discussing dosage and tolerance, we felt that it would be of value to study our records and to compare the amount of alkaloid required to terminate an attack at the onset of therapy (ergotamine tartrate) with the minimum effective dose after the drug had been administered for over a year. To our amazement we found that not only were none of the patients requiring more of the medication but many of them were requiring smaller doses now than at the onset. I do not wish to leave the impression, however, that we believe that this lessened dosage is due to any effect from ergotamine tartrate, that would not be correct. It is probably caused by several other factors.

In the first place, we have observed that the earlier in the attack the drug is given the smaller is the dosage

required. Once the episode has reached its peak, the patient prostrated, vomiting and unable to raise his head from the pillow, a much larger dose is necessary to check the attack, and it takes much longer for any amount to give relief. The after-effects of both the headache and the ergotamine are much more disagreeable.

If patients will take the medication the moment they feel the prodromes and are sure that they "are in for a real one," the attack may be completely aborted by a smaller dose in much less time and the untoward effects of the drug will be greatly lessened.

From our experience, after using many experimental procedures in attempting to find a cure for migraine, we have concluded that ergotamine tartrate may be used in conjunction with these other measures without coloring their results. Therefore, we have given this drug during the administration of an expected cure in order to control those attacks which may break through. This explains why many of our patients now require a smaller dose of ergotamine tartrate to check the attacks than they did at the onset of therapy, because these preventive measures have been lessening the severity of the episodes and likewise decreasing the minimum effective dose.

Any disease that will incapacitate an adult, interfering with his work for a day or more from one to four times a month is a definite economic liability. Eighty-four persons in this series suffered from migraine attacks at least once a month or more. The time necessary for ergotamine tartrate to effect complete cessation of the episode, even though it would ordinarily persist for from two to three days when given hypodermically, was from fifteen minutes to five hours. This varied in individual cases with the dosage, with the time of administration and with the severity of the attack. We have calculated from our records that the subjects in our series were freed from approximately 39,000 hours of suffering.

Three individuals whose attacks always occurred in the middle of the night or the early morning, awakening them from their sleep, would get out of bed, take their medicine, return to bed, awaken the next morning and go to work as if nothing had happened. Without this drug they would have been incapacitated from their work for at least an entire day.

One woman who is at the menopausal age and whose attacks have been coming weekly during the entire year and continuing for two or three days has stated over and over again that she does not know how she would exist if it were not for this medication. She is a school teacher and by necessity self supporting. Without the medicine she believes that she could not carry on.

Concerning the administration and dosage of ergotamine tartrate, there are several points worthy of discussion. In this country the drug² is prepared in tablets containing 1 mg of the alkaloid and it is also marketed in solution in sterile ampules for intramuscular and intravenous use (0.25 mg = 0.5 cc and 0.5 mg = 1 cc). Some investigators have applied the drug to the nasal mucous membranes,³ others have incorporated it into suppositories for rectal absorption.

Our method of administering the drug subcutaneously is to inject a trial dose of 0.25 mg, and the effectiveness of this we use as an index to future medication. If the drug is well tolerated and if it

² Trade name Gynergen manufactured by Sandoz Chemical Works Inc. to whom we are indebted for a liberal supply of this alkaloid for our investigations.
³ von Storch T. I. C. Personal communication to the author.

terminates the attack within two hours, we consider that dosage a satisfactory one for future episodes. It is advisable to repeat the initial dosage of 0.25 mg if after two or three hours the headache persists, or if after from eight to twelve hours the attack returns. If repetition has been necessary, we consider our original order inadequate and for future attacks 0.5 mg is given.

We have never injected a larger dose than 0.75 mg of ergotamine tartrate subcutaneously to relieve one attack, and this amount has been used only three times in our investigations. It is quite rare that a patient needs more than 0.5 mg, and this is a usual and safe amount.

ORAL USE

In dispensing the alkaloid orally we have observed that if the required amount is taken at once, rather than in divided doses, a more efficient relief will be obtained. One tablet contains 1 mg of the alkaloid. We have given as many as five of these at one time to check an attack. If as large a dose as this is used, we would strongly advise against administering any more ergotamine tartrate within twelve to twenty-four hours.

If, before the medication is given, nausea and vomiting have set in, it is useless to dispense the tablets. They will probably only increase this condition and will interfere with the use of the medicine hypodermically.

It has been suggested that the ergotamine tartrate by mouth, one tablet three times a day, will prevent the migraine attacks from appearing.⁴ We do not recommend this method of dispensing the drug. Migraine is a protracted condition and we do not know what serious effects the daily use of the drug over long periods of time may have on our patients.

Although this form of medication may prolong the interval in between the periods and although it may abort some of the milder headaches and even diminish the intensity of a few of the more severe ones, it will not completely inhibit or cure the pathologic condition.

In the third place, the migraine attacks occur very irregularly and undependably in most patients. To give as costly a medicament as ergotamine tartrate daily, when if no medication were taken the patient might go for several weeks without an attack, is wasteful. In a patient who has been suffering from weekly or biweekly headaches the attacks may spontaneously come at monthly or bivearly intervals, and the medication would have been given in vain.

Early in our investigations we tested the value of this method of therapy and found it unsuccessful. One of these patients, after the foregoing method of dispensation failed, took the pills, two or three at a time, the minute she felt an attack appearing. This dosage seemed to stall off an episode for that day, but it usually reappeared on the following one, necessitating further therapy. She continued in this manner for several months and was taking, therefore, two or three pills daily, or approximately 10 to 21 mg of the alkaloid a week. We have advised against this medication and are administering the drug hypodermically. If the attacks occur twice a week she receives only 0.5 to 1 mg a week because her headaches are completely terminated by 0.25 to 0.375 mg when the alkaloid is given subcutaneously.

The results of the alkaloid no matter how administered will be much more satisfactory if the drug is used early in the attack. As soon as the patient realizes that an episode is inescapable the prescribed dosage

should be taken. If the injection or the pills are given during the peak, with the patient vomiting and prostrated, the headache will be more difficult to control. The beginning of an attack and the tail end are readily checked by a smaller dose.

It is most important that the patients lie down after the medication. A headache that can be checked within one to two hours may be considerably lengthened unless the patient relaxes after its administration. Our routine clinic order is to rest for from one to two hours or until the headache has completely disappeared.

The results obtained from the use of ergotamine tartrate orally and hypodermically in controlling the migraine attacks are so dissimilar that it is necessary to discuss them separately. A statement which is an accurate description of the effects following hypodermic injection cannot be applied to the response obtained from the tablets. All the previous assertions concern the reactions that occur after the subcutaneous use of the alkaloid.

We have dispensed the tablets to forty-five patients and only thirty-one of them obtained complete relief, this does not equal the 92 per cent of patients who were benefited by the injection. The time required by the tablets before termination of the attack can be expected varies from one to eight hours, averaging about five hours. The average time required for the injection to check the attack is from one to three hours.

The theory of the individual infallibility of ergotamine tartrate, once it has relieved an attack, is fallacious when applied to the effect of the tablets in relieving the headaches. Their beneficial action is dependent on too many factors, such as the state of the gastro-intestinal tract at the time of dosage, the severity of the attack, and the time of administration of the drug. No matter how many times tablets have aborted a headache, if there is severe nausea, if the attack is too intense, or if their administration has been delayed too long, the oral use of ergotamine tartrate may fail to give relief.

Because the tablets are less dependable does not mean that they should not be dispensed for relief of the episodes. Their advantage over the hypodermic use of the drug is obvious and any medication that benefits 69 per cent of the migraine patients is of definite value in the treatment of this enigma. I have stressed these differences in action between the two forms of the alkaloid because I feel that one should not condemn the drug because of the failure to check the headache following its oral administration.

CONCOMITANT SYMPTOMS AND THEIR ALLEVIATION

Although ergotamine tartrate, subcutaneously, caused abrupt termination of 1,042 headaches in eighty-nine patients and, when given orally, it completely checked sixty-three headaches in thirty-one patients, it did produce uncomfortable concomitant symptoms in many individuals.

These untoward effects were nausea, vomiting, weakness of the legs, stiffness of the joints, a sense of constriction in the throat, a heaviness of the chest, and a burning and tingling of the fingers and toes.

These symptoms did not all occur in the same patient at one time. Forty-two patients vomited after ergotamine tartrate. In eighty-three of our patients nausea and vomiting were associated with the headaches even before any medication was given. There was no direct relationship between the occurrence of the gastric symptoms before and after the medicament. Five patients

⁴ Podalsky, A. West Virginia M. J. 20, 173 (April) 1933. Trautmann, E. Munchen med. Wchnschr. 55, 513 (March 21) 1928.

vomited after the drug, and in these individuals there has not been any gastric complaints with the attack. Ten persons who did not suffer from nausea and vomiting with the headaches felt no gastric distress after the drug.

Twenty persons who suffered from these gastric disturbances before the medication were indifferent to their occurrence after ergotamine tartrate because they associated vomiting with relief of the attacks and rather expected it.

In ten patients, if the medicament was given early enough in the episode the entire attack could be aborted, the headache effaced and the individual entirely well before the gastric symptoms had a chance to develop. In these persons, if the attack should continue to its peak, these gastric disturbances would become very intense.

When the nausea and vomiting following ergotamine tartrate therapy are severe enough to disturb the patients, atropine $\frac{1}{100}$ grain (0.0006 Gm.) injected with the alkaloid, or any time after its use, will alleviate this distress. It was necessary for us to use this combination on only twelve occasions, because we were able by our concurrent therapy—the administration of calcium⁵ chondroitin sulfuric acid⁵ or an estrogenic preparation (progyon)⁶—to diminish the vomiting occurring both with the migraine attacks and after the administration of the drug. These gastric disturbances were by far the most frequent of the untoward results of the drug. Nineteen of our patients, however, described muscle pains following the injection. In three of them they were very severe and continued for a day after the headache had been abolished. The milder forms of this muscle pain were described by a few other persons as a restlessness and an inability to find a comfortable spot for their arms and legs.

Calcium gluconate 10 cc intravenously will relieve these muscle pains almost immediately, and daily calcium therapy will diminish or prevent their recurrence. Atropine hypodermically or orally, in the foregoing dosage, has inhibited and relieved them on several occasions.

Thirty-seven of our patients complained of generalized weakness associated with the migraine attack. Fifteen individuals stated that, after the alkaloid had eliminated the headache, their legs felt tired and weak. It is rather difficult to determine whether this asthenia was caused by the drug or whether it was a coexistent migraine phenomenon that the drug was unable to eliminate. A few of the patients state with certainty that this "all in" feeling is more noticeable to them after the drug than before.

One patient who left the clinic without obeying our routine instructions of lying down for an hour after the medication fell down a flight of clinic steps. She described the accident by saying "My legs just gave way, my knees buckled under me."

Ergotamine tartrate caused a stiffness of the joints in four individuals, in two it affected the jaw, in one the shoulder and in another the ankles.

Two persons felt a slight heaviness in the chest "as if a weight had been placed there," a feeling that made them want to take a deep breath. Six others said that there was a constriction in the throat, "a funny sensation." This did not seem to be particularly disturbing to any of them and occurred rarely.

Two patients complained of numbness and burning of the fingers, which was increased when the hands

were placed in very hot or very cold water. We observed on two occasions a painful swelling and redness of the fingers and toes after we had administered ergotamine tartrate and atropine to one of our ward patients. This woman has since received several injections of ergotamine tartrate alone when this did not occur.

SIGNIFICANCE OF SYMPTOMS

To those who are familiar with the signs and symptoms of ergotism and its complications, some of these symptoms are portentous. I do not know what the effect of the continued use of this drug may be. I have searched for pathologic changes in electrocardiographic studies on those patients who have taken medication for eighteen months or more and have made frequent blood pressure, blood sugar and kidney studies but have never found any organic changes.

Migraine is a chronic ailment, however, and may last from twenty to forty years. What the action of this medicament on the vascular system will be if used for that length of time, no one can say.

It is important, therefore, to consider this affliction as a syndrome and not as a disease entity, and to realize that more than one factor can precipitate an attack in the migrainous individual. Unless one studies patients and treats any pathologic process, including psychic factors, that may be present, one may be injuring the future health of these persons by administering this alkaloid in large doses over long periods of time. If, however, each individual is carefully studied and if any abnormality—ophthalmologic, gastro-intestinal, functional, infectious, glandular or allergic—that may be present is treated, the severity and frequency of the episodes can at least be lessened. In this manner we have in many instances⁶ reduced the yearly intake of the alkaloid to an almost negligible quantity.

Spontaneous cessation of the attacks in migraine is a characteristic observation. In almost any therapeutic and statistical study of the syndrome one can report complete cessation of the attacks in a few patients. In this series two women, both at the menopausal age, have now been without episodes for more than eighteen months. Neither of them had received more than two injections and both of them had suffered from migraine all their lives at monthly intervals.

That psychic factors can precipitate attacks in migrainous persons, most of us who have had any experience with the syndrome will not deny. That they are the only factors in the production of the episode is not in accordance with the observations of this clinic. That psychic factors alone can completely check 1,000 full-blown migraine attacks within from fifteen minutes to two hours, I challenge.

Considering this possibility at the beginning of the investigations, we administered almost all our medications subcutaneously. Because of this, we were able to inject sterile water, pitressin, epinephrine, mecholol, and the like without the patient's knowledge of the contents of the syringe. During an attack, after we had attempted to give relief by several of these measures and they had failed, we would administer ergotamine tartrate. Occasionally some other medicament would alleviate the attack, but there was no comparison between the character, the frequency or the constancy of the relief obtained from these preparations and from the alkaloid of ergot. The results of other workers substantiate further the belief that the pharmacologic action of ergotamine tartrate in checking the episode is not merely a suggestive one.

⁵ To be reported

The use of this alkaloid in the treatment of migraine is not a particularly recent therapeutic measure. Lennox and von Storch⁶ in their latest discussion of this therapy have totaled the number of cases reported in the literature. They state that the dozen authors who have given the drug to 300 patients agree that the administration of ergotamine tartrate is effective in stopping migraine headache in the great majority of patients.

How the alkaloid checks the attacks no one really knows. From our experience in this clinic we do not believe that the therapeutic action is merely analgesic. One patient, who received ergotamine tartrate during a headache, had been suffering simultaneously from a toothache. Ergotamine tartrate checked the migraine attack but gave no relief to the molar pain.

Another man, who entered the hospital because of a severe continuous pain in the ulnar nerve, the result of a gunshot injury, developed, while in the ward, one of his biyearly migraine attacks. He had suffered from migraine all his life. The alkaloid was injected and the headache was abolished. The intense pain in his hand, however, was unaffected.

The theory that the pharmacologic reaction of ergotamine tartrate which relieves the migraine attack occurs at the sensory endings is not consistent with the foregoing. Nor does it explain the large number of headaches that occasionally occur in normal people following its injection. We have given the alkaloid to patients suffering from various types of headache that have not in the least resembled migraine. These headaches are usually unaffected by the alkaloid.

Because of the high percentage (90) of satisfactory results obtained by using ergotamine tartrate in the treatment of the migraine attack, in comparison with the very low percentage of satisfactory results obtained by using it in the treatment of those headaches occurring in the general medical wards, we believe that the reactivity of the drug is more intimately related to the pathophysiologic mechanism of the migraine attack than is suggested by ascribing its action to an analgesic effect. We do not consider the reaction to be a direct one but believe that the action of the alkaloid seems to be dependent on the humoral state of the organism.

The suggestion that the effectiveness of the alkaloid varies with the chemicals and hormones circulating in the blood is based on the differences that occur following administration of the drug to obstetric patients, as well as on the differences occurring when the drug is administered along with other medicaments, for example, calcium, epinephrine, atropine and some of the glandular products.

It is very rare for the obstetrician to see the many untoward results that we have noticed following the use of the alkaloid in normal and migrainous patients. The obstetrician casually prescribes doses which from his experience he knows to be perfectly safe and effective, but doses which we would be extremely cautious in using. This increased tolerance to the drug at parturition, this failure to relieve the general medical headache, the abrupt termination of the classic migrainous attack, have led us to the assumption that the activity of the drug does not merely effect a paralysis of sensory nerve endings but is more intimately connected with the complex mechanism of the still unexplainable migraine seizure.

SUMMARY

1 Ergotamine tartrate was administered to ninety-seven patients and checked or aborted 1,042 attacks in eighty-nine of these persons.

2 It was calculated that the individuals in our series were relieved from 39,000 hours of suffering.

3 The earlier in the attack the medication is given the better are the results.

4 When used subcutaneously, the alkaloid has never failed to check again an attack in a person previously relieved if the drug was given in adequate dosage.

5 Untoward effects of the drug may be relieved by simultaneous injection of $\frac{1}{100}$ grain of atropine or calcium gluconate intravenously.

6 I do not consider the drug a cure for migraine. I strongly advise against its dispensation without a consideration of the cause and prevention of the syndrome.

CONCLUSION

Because of the constancy and character of the relief obtained from 1,042 headaches in eighty-nine sufferers of migraine after the administration of ergotamine tartrate, I recommend its use for the termination of these attacks and believe that the drug is a valuable addition to medical therapeutics.

Clinical Notes, Suggestions and New Instruments

DUPLICATING FILMS OF ROENTGENOGRAMS

MAX COHN, M.D., CHICAGO

The making of roentgenograms in a hospital occasionally leads to a controversy between the patient, the physician and the roentgenologist over ownership of the original film.

Positive prints from roentgenograms are unsatisfactory and except in certain simple cases the fine details of the original are inadequately reproduced.

Until recently it was necessary for the maker of a roentgenogram either to protect himself by keeping the film in his possession or to satisfy the physician and the patient at the risk of criticism, should he be unable to produce the film for medical or legal purposes at some future time.

A new photographic material called "Direct Duplicating Film" is now available. With this film any number of exact duplicates can be produced from original roentgenograms by direct contact printing without the necessity of making an intermediate film with consequent loss of detail. The film has characteristics exactly opposite those of normal photographic film.

If developed by a safelight without having been exposed to light, Direct Duplicating film becomes entirely black, developing to maximum density. If, however, the film is completely exposed to white light and then developed, the film remains clear and transparent. This material forms a positive image directly from a positive, becoming clear and transparent when exposed to transparent areas of the film being copied and becoming progressively darker and more opaque as the film to which it is exposed becomes darker and more opaque.

Developing, fixing and washing correspond in every way to the ordinary handling of any other film. Provided exposure and processing are correct, the duplicate will for practical purposes equal the original. The duplicating film is a so-called "safely" film.

In making a duplicate of a roentgenogram it is possible to print a caption on the duplicating film which may be an identification or may correspond to an official certification that the

⁶ Lennox, W. C., and von Storch, T. J. C. Experience with Ergotamine Tartrate in 100 Patients with Migraine. *J. A. M. A.* 105: 169 (Dec. 2) 1935.

From the X-Ray Department, Mount Sinai Hospital, 1 Arlo A. Co. Corporation, Longham, N. Y. Available in General Electric Company.

film was taken during an examination made on a certain date by a certain person, and that the original film is on file at a designated hospital or radiologic clinic.

The possession of direct duplicates of roentgenograms would often allow the patient in accident insurance cases not only to recover the cost of examination but, through possession of adequate evidence to guard against an unwarranted increase in premium at a later time.

In the course of a series of examinations for life insurance or for recording pathologic changes over a period of time duplicate x-ray films could be included with copies of the physician's report.

The roentgenologist seldom cares to give away the originals of rare films, and because of the difficulties that formerly prevented satisfactory photographic reproduction of roentgenograms and the totally unsatisfactory nature of most printed reproductions the widespread circulation and study of many valuable films has been impossible.

With Direct Duplicating films, satisfactory duplicates can at last be made and the duplicates circulated in medical and educational institutions like prints from an ordinary photograph. By printing the maker's signature on the duplicating film when the original roentgenogram is being reproduced the duplicating film is acceptable as evidence in case of litigation.

SOLUTION OF THE NEEDLE AND THREAD PROBLEM

J. EASTMAN SHEEHAN, M.D., NEW YORK

For delicate suturing, the needle with an eye was larger at the head than in the shaft and so produced an aperture in the skin that was needlessly large. But its life was good for several threads. To overcome the major defect the thread was inserted in the body of the needle, allowing shaft and head to be of one thickness. But the life of the needle was then the life of one thread.

A needle with suture thread and screw head assembled B parts separate C with forceps to attach and detach

The needle here portrayed, of my design readjusts the balance. The problem of dimension is solved by retaining the thread enclosed in the needle body. But when the thread has been used it may be discarded together with the fitting that holds it by the simple process of unscrewing that fixture. Another thread with similar screw attachment is then sub-

stituted, and the suturing goes on without the needle even being withdrawn. This is repeated as long as the needle is sharp enough for its purpose when a new or unfinished thread is attached to a new needle. About six threads can be so used with one needle, and the supply is arranged on that basis.

DRUGS USED IN THE TREATMENT OF CIRCULATORY FAILURE IN ACUTE INFECTIOUS DISEASES

CARY EGGLESTON, M.D.

Assistant Professor of Clinical Medicine, Cornell University Medical College, Visiting Physician Second (Cornell) Medical Division, Bellevue Hospital, Associate Attending Physician, New York Hospital, NEW YORK

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION.—Ed

The discussion of the use of drugs in the treatment of the circulatory failure seen in acute infectious disease is fraught with difficulty because of the limitations of our knowledge of the mechanisms responsible for the failure. Clinically the usual type of failure appears to be due to loss of peripheral vascular tone or a vasomotor paralysis. Much less commonly the evidence seems to point to a primary failure of the heart. In many instances both vasomotor and myocardial failure appear to participate to varying degrees. It is unfortunately not always possible clinically to assess the relative part played by either form of failure, so that treatment frequently cannot be based on a clear concept of the mechanism or mechanisms involved.

In bacterial endocarditis, acute rheumatic fever and diphtheria the heart is known to be damaged directly. But even in these diseases there is no unanimity of opinion as to the mechanism of the circulatory failure that may develop. In some cases it seems clearly to be of cardiac origin, and there are many clinicians who accept this as the established mechanism. The presence of cyanosis, congestion of the lungs, occasionally some dyspnea, and distention of the veins definitely indicates myocardial failure. But in most instances these are more or less masked by signs and symptoms referable to peripheral vascular failure. The latter include pallor, extreme weakness, sweating, decreased blood pressure, low pulse pressure and rapid, feeble pulse with poor heart sounds; these are the manifestations of shock or collapse. Because of the frequent presence of the latter symptoms, many believe that even in diphtheria, rheumatism and bacterial endocarditis, the circulatory failure usually is due to the participation of both cardiac and vasomotor mechanisms.

It is now generally accepted that the other acute infections cause little or no direct myocardial damage except the cloudy swelling common to febrile and infectious processes. The circulatory failure in these is concededly of the vasomotor type. The acceptance of this concept, however, does little to simplify the problem of treatment, since one or more of several factors

may be responsible for the failure of the vasomotor mechanisms. Despite extensive clinical and experimental investigations, knowledge of the various factors is still far from complete. Severe, acute dehydration may be produced by excessive sweating, vomiting or diarrhea, alone or in combination. It may cause a sufficient fall in blood volume to reduce the output of the heart so greatly that the vasomotor center begins to fail and thus initiates a rapidly fatal collapse. Unless promptly checked, this process may be complicated by the effects of toxins arising from dehydration itself as well as from the inadequate blood supply to the tissues. It is known that histamine and guanidine may be produced in excess under such circumstances. Through direct action on the blood vessels these toxins may cause great vascular dilatation with secondary marked reduction in both blood pressure and cardiac output and either initiate or aggravate extreme circulatory collapse. It is probable in acute infections that yet other toxic substances may arise which can produce the vasomotor form of collapse.

The vasomotor center may remain functionally active, as has been demonstrated in the collapse produced in both pneumonia and diphtheria. In diphtheria there is reason to believe that the toxin may act directly on some portion of the splanchnic nerves to produce wide dilatation of the splanchnic blood vessels. This, in turn, may be sufficient to induce an excessive fall in blood pressure and a secondary depression of the vasomotor center as previously described. Finally, it is known that acute circulatory collapse may be caused by reflexes acting through the central nervous system, and it is possible that similar effects may be produced through the direct action of toxins arising in the course of some of the acute infections such as meningitis.

The preceding brief review of some of the more likely mechanisms that may be involved in the causation of circulatory failure and the great difficulty of reaching a correct mechanistic diagnosis justifies the contention that most of the treatment recommended is largely empirical. Christian¹ is right in his statement regarding the treatment of circulatory failure when he says "Of those recovering, more get well than are cured." The following discussion of drugs is presented in the light of the foregoing review of the problems.

Caffeine is probably the most widely used drug. Its actions are diverse and not very readily controllable. Through direct stimulation of the higher portions of the central nervous system, it may diminish the patient's exhaustion and improve his sense of well being. By direct action on the medullary centers, it stimulates respiration and to a variable extent also stimulates the vasomotor center and may tend thereby to raise the blood pressure and improve vascular tone. Through direct action on the heart muscle it may raise its tone, increase both the strength and completeness of its systole, promote diastolic relaxation, and, if it does not cause too much acceleration in the heart rate, may result in an increase of the cardiac output. These actions may be further enhanced by some improvement of the coronary circulation by a specific dilatation of those vessels. On the other hand in susceptible individuals or when the dose is too large it may prove harmful by causing mental excitement, insomnia and marked irritability. Large doses may also produce harmful tachycardia and directly impair cardiac output by diminishing diastolic relaxation. If either of these

detrimental effects is produced, its administration should be stopped or the dose reduced. It is generally best administered hypodermically in the form of a sterile solution of Caffeine with Sodium Benzoate. The average single dose lies between 0.3 and 1 Gm. Its frequency of repetition should be guided by its effectiveness and the presence of indications for its further administration rather than on any arbitrary schedule. Its action usually lasts about two hours but seldom for much longer. It should be regarded as an emergency remedy and its use stopped when it is no longer needed. It may be administered intravenously by slow injection through a small needle. Its rapid injection is distinctly dangerous. The other purine derivatives, such as theophylline and its compounds and theobromine, are too feeble as compared to caffeine in their actions as cardiac and vasomotor stimulants to be of value in the treatment of circulatory failure.

Strychnine is believed by some to be valuable by others to be useless. If it is to be used it should be administered in doses much larger than are commonly employed. At least 0.002 Gm is required, and single doses of from 0.003 to 0.006 Gm are more certainly effective. It should be administered hypodermically. The dose may have to be repeated every three to six hours. The patient should be observed closely for the possible appearance of reflex hyperexcitability. Its mode of action is chiefly indirect as a result of increased nerve irritability, which enhances the tone of the heart and blood vessels. Its administration is unfortunately without benefit unless it is employed in doses verging on the toxic, and many of the failures have been due to the fear of giving it in adequate doses.

More certainly effective than any other agent for the promotion of peripheral vasoconstriction is epinephrine. This should be administered in the form of the solution of Epinephrine Hydrochloride, which may be injected intramuscularly in doses of from 0.6 to 1 cc, or the same doses can be made much more effective, yet safe, if injected slowly and continuously into a vein. For the latter mode of administration 1 cc of the solution may be added to a liter of physiologic solution of sodium chloride or to the same volume of 5 per cent solution of dextrose. By these procedures one combines the prolonged maintenance of vasoconstriction at a readily controllable level with the restoration of both fluid and salt or dextrose. Both fluid and salt are of great value when much has been lost through diarrhea, vomiting or sweating. From 1 to 3 liters of such solutions may be infused slowly during twenty-four hours in desperate cases.

The intramuscular injection of epinephrine may elevate the blood pressure and stimulate the heart but these effects are generally slight and inadequate, and of brief duration. This is due to the intense local vasoconstriction at the site of injection, which further impairs absorption already reduced by the failing circulation. Absorption may be promoted and the action of the drug somewhat prolonged by occasional massage of the site of injection. The actions of epinephrine can occur only after absorption into the blood stream and they are of short duration unless the drug is supplied in adequate concentration either continuously or at brief intervals. It is theoretically the best of all available drugs for use in peripheral circulatory failure for it acts directly on the endings of the vasomotor nerves to produce vascular constriction and elevation of blood

¹ Christian, H. A. The Diagnosis and Treatment of Diseases of the Heart. Oxford University Press, p. 53.

pressure, and at the same time it stimulates the heart through the sympathetic nerve mechanism as well as by a probable direct action on the myocardium. It is contraindicated in those patients whose blood volume has been much reduced by loss of water through diarrhea or sweating. This is because vasoconstriction takes place as a natural compensatory mechanism under such circumstances. If this constriction passes an optimal degree, it aggravates the circulatory failure by interfering with return flow to the heart and thus further reduces the heart's minute volume output. Its use in improperly selected cases may aggravate the condition to relieve which it was given.

Both Ephedrine and Solution of Posterior Pituitary have vasoconstrictor actions which result in some elevation of the blood pressure. Their actions can be secured by subcutaneous or intramuscular administration if the circulation is adequate to permit their absorption. Hence they are best used at the inception of circulatory failure, or even prophylactically when its development seems imminent. Unfortunately, in actual practice they have not proved either of much value or very trustworthy, and the too frequent repetition of pituitary may lead to depression of the tone of the vasoconstrictor system with resulting fall in blood pressure. Ephedrine Sulfate or Hydrochloride may be used in single doses of from 0.03 to 0.1 Gm. for an adult. It may be repeated according to the patient's needs, but frequent or large doses often cause rather excessive nervousness and sometimes produce vomiting. Pituitary is best given in a single dose of from 0.5 to 1 cc. of the official solution. This may be repeated at intervals of one to four hours, but it is seldom either wise or necessary to repeat more than two or three times, as further doses rarely prove of value.

Digitalis and strophanthin are of no value in the forms of collapse not due to failure of the myocardium. They are, in fact, often harmful and should be regarded as definitely contraindicated. Even in those instances in which circulatory failure appears primarily due to cardiac failure, however, these agents usually prove worthless. This may be ascribed to their inadequate absorption, to their inability to offset the more powerful actions of the toxins already influencing the heart, to the fact that the heart in such patients is too severely damaged to respond to any stimulation, or to the simultaneous presence of peripheral vascular failure. Whatever the true explanation, the fact remains well established that members of the digitalis group of drugs are either contraindicated in the circulatory failure of acute infections or prove wholly ineffective in its attempted control.

Camphor and the unofficial substitutes, such as cardiazol or homocamfin, are too untrustworthy to deserve mention. Whatever stimulant actions they may occasionally produce are chiefly on the respiratory center or reflexly through local irritation of the tissues at the site of administration. Even these slight actions are too fleeting to be of any considerable value.

Experience seems to indicate that the most promising plan of treatment should include one or more of the following procedures in addition to such preventive measures as the provision of rest, adequate and balanced diet, sufficient fluids during the course of the acute illness, and the administration of oxygen by nasal catheter or tent when indicated by the presence of cyanosis, anemia or anoxemia. From 50 to 100 cc. of 50 per cent dextrose solution should be administered

intravenously once or twice in twenty-four hours. Caffeine or strychnine, as previously discussed, should be injected promptly at the first evidence of failure. If the loss of fluid and salt has been excessive, slow intravenous infusions of physiologic solution of sodium chloride should be given in amounts of 1 to 2 liters. The heart will not be overtaxed by too large a volume of fluid if the injection is stopped at the beginning of a rise in the venous pressure, which now can be measured easily by the direct manometric method. In cases associated with intense diarrhea, infusions of not over 300 cc. of a 5 per cent solution of sodium chloride may be most valuable. Transfusions of blood, if feasible, may help materially. Only when these measures are unavailing is it wise to resort to the addition of epinephrine to the transfusion or the simultaneous injection of either ephedrine or posterior pituitary.

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORTS HOWARD A. CARTER, Secretary

THE PRESENT STATUS OF FEVER THERAPY PRODUCED BY PHYSICAL MEANS

FRANK H. KRUSEN, M.D.

ROCHESTER, MINN.

During the past year, interest in the production of fever by physical means has greatly increased. More than a hundred articles on the subject have been written during 1935.

METHODS OF TREATMENT

Artificial fever has been induced by means of the following physical agents:

Radiant Heat—The air conditioned cabinet is the most recent development in this field. Although these cabinets do not produce a rise in bodily temperature by direct application of radiant heat to the surface of the body but rather by the heating of circulated air, which is blown over the body, they may still be classed as radiant heat devices. The hyperpyrexia is produced by the heated air. Much excellent clinical work has been done with this type of apparatus during the past year. The construction of this device has been described by various investigators.¹ The device is elaborate, requires a skilled team of workers for its operation and is not on the market at present. There are approximately fifty-five of these cabinets scattered throughout the country at various medical centers for purposes of clinical research.

Atsatt and Patterson² have described a device for the production of artificial fever by means of conditioned air, which they stated could be constructed by any competent hospital engineer at a cost that was considerably under \$100. They described this device in detail so that it can be reproduced by following their diagrams and description.

From the Section on Physical Therapy, the Mayo Clinic.

2. Atsatt, R. F. and Patterson, L. E. Fever Therapy Apparatus. *Arch. Physical Therapy* 18: 108-110 (Feb.) 1936.

Luminous Heat Cabinets—Such cabinets have been used for the production of fever.³ These cabinets do not possess the features of air humidification and air circulation found in the previously mentioned cabinet. Bishop, Lehman and Warren,³ who described the luminous heat cabinet, stated that "humidity control of the air in the radiant energy cabinet was investigated and was found to be of little benefit in the set-up described, especially in view of the complications that it imposed." It has been my experience, however, that the lack of proper humidification is somewhat of a disadvantage. There is one other disadvantage in this cabinet as described by the men who devised it, that is, the heat insulation of the cabinet is insufficient. Bishop, Lehman and Warren,³ however, stated that the radiant energy method described seemed to be the most convenient and economical method in their experience. They also stated that the cost of their cabinet was approximately \$150 and they gave an excellent description of its construction in their article.

It is likewise worth noting that Johnson, Osborne and Scupham⁴ believed that the ordinary electric light cabinet was the safest method for the production of artificial fever by physical means.

Nonluminous Heat Cabinets—There have been marketed by various manufacturers cabinets which somewhat resemble the one described by Bishop, Lehman and Warren,³ with the exception that the cabinets are heated by resistance heat coils somewhat similar to the coils found in the familiar household electric heater. Some of these devices have been humidified by means of a water trough within the cabinet. This method of humidification, however, is most unsatisfactory. None of these devices have yet been accepted by the Council on Physical Therapy as a satisfactory device for the production of fever.

Electric Blankets—Various kinds of electric blankets, frequently constructed somewhat like a large sleeping bag, have been used for fever therapy. They are less expensive than the cabinets, but a great disadvantage is that the patient is closely confined by the blanket. Kuhns,⁵ after four years of trial, expressed the opinion that the electric blanket is "the simplest and safest form of fever producing agent." These electric blankets, however, may be used satisfactorily only in those cases in which a fever of not over 103 to 104 F is required. For higher temperatures than this they are not at all satisfactory. The patients are made most uncomfortable by the close confinement of the blanket.

High Frequency Electrical Method—This method of treatment first described in 1929,⁶ is still being used, although it has been replaced to a certain extent by recently developed devices. The ordinary diathermy machine is used and large metal electrodes are applied to the patient's skin in such a manner that a large region of the body is traversed by the high frequency current. The patient is then covered by blankets or

placed in a sleeping bag or a heat cabinet to prevent dissipation of the heat produced in the body by the high frequency current.

Short Wave Diathermy—The short wave diathermy machine is somewhat similar to the conventional diathermy machine with the exception that the oscillations of current are much more rapid (conventional diathermy machines produce approximately 2,000,000 oscillations per second as compared to short wave diathermy machines, which may produce 100,000,000 or more oscillations per second). The heating of the body of the patient may be produced either by the induction coil or by the condenser plate method. With the induction coil method a coil of heavily insulated wire or ribbon is attached to the machine. This coil is either wound around the nude body of the patient or placed close to the surface of the patient's body in the form of a large pancake, and the patient is then heated by means of the high frequency electromagnetic field that is produced. Insulation of the patient's body is accomplished by means of blankets, a zipper bag or an insulated cabinet. One such method has been described by Kimble, Holmquest and Marshall.

With the condenser plate method essentially the same arrangement is used as with the induction coil technic, with the exception that the coil is replaced by two large condenser plates, which are placed on each side of the patient in such a manner that a large portion of the patient's body is within an electrostatic field between the plates. The body is then heated by the high frequency waves that pass between the two plates. Insulation of the patient's body is accomplished as previously mentioned.

One of the disadvantages of short wave diathermy is the tendency for the production of burning sensations on the moistened skin when the patient begins to perspire. In addition, when the patient assumes a posture in which two surfaces of the skin are touched together very lightly, burning is likely to occur at the site of contact. For this reason a number of investigators⁷ have abandoned the use of high frequency currents in favor of some form of external heat cabinet.

Hydrotherapeutic Methods—**Hot Tub Baths** The production of fever with hot baths, which was described by Phillips in 1883, by Schamberg and Tseng in 1927, and by Mehrtens and Pouppirt in 1929, is still being used successfully by some investigators. Although prolonged hot tub baths are depressing, nevertheless the patient's temperature may be raised rather rapidly, and it may be maintained at a fairly high level for an hour or two by this method alone. The hot tub bath may be used to induce artificial fever, the fever being maintained, after induction, by means of blankets or a very simple radiant heat cabinet.

Hot Spray Baths The nude patient may be placed in a horizontal position in a cabinet similar in external construction to the radiant heat cabinet and he may then be sprayed with a series of very fine jets of nebulized, very hot water, the temperature of which is controlled by means of a thermostat. Such a spray cabinet will produce a rapid rise in bodily temperature if the temperature of the water can be maintained at the proper degree. Difficulty may be encountered in maintaining the bodily temperature at the necessary high level in such a device.

Conduction Heat Methods Other Than the Foregoing—Epstein and Cohen⁹ have devised a simple method of inducing hyperpyrexia by wrapping the patient in blankets and rubber sheeting. With this method no source of heat other than the natural heat radiation of the body is utilized. However a period of four or five hours is necessary simply to raise the temperature to 104 F., which would seem to subject the patient to an unnecessarily long period of discomfort before the required high temperature is achieved. If this method is to be used, it would seem expedient to use at least a few hot water bottles incorporated in the wrappings of the patient in order to make the induction of fever more rapid and to relieve the patient of several hours of unnecessary discomfort.

Hot Water Bottle and Blanket Method—Haddon and Wilson¹⁰ described this method which is still used quite frequently. The patient is simply wrapped in a number of thick blankets and surrounded by hot water bottles. The great disadvantage of any blanket method rests in the fact that nearly all patients are made extremely uncomfortable by the confinement of their limbs by the necessary tight wrapping of so many heavy coverings.

DISEASES TREATED

It is amazing to find that during the past year the use of fever produced by physical means has been recommended for no less than fifty different diseases. The results in the treatment of the majority of these diseases have not been encouraging, although for a selected few the method of treatment has given promise of great usefulness. In 1935 artificial fever produced by physical means was used in the treatment of the following conditions: adiposis dolorosa,¹¹ allergic dermatitis,¹² arteriosclerosis,¹¹ bacterial endocarditis (subacute),¹³ bronchial asthma,¹⁴ bronchiectasis,¹⁵ Burger's disease,¹⁰ cerebral atrophy (with chronic otitis media),¹⁷ chorea,¹⁸ chronic sinusitis,¹⁰ dermatitis herpetiformis,²⁰ epidemic encephalitis,²¹ epi-

lepsy,¹¹ "gallbladder infections,"¹¹ gonorrhea,²² gonorrheal arthritis,²³ gonorrheal corneal ulcer,²⁴ gonorrheal endocervicitis,²⁵ gonorrheal epididymitis,²⁶ gonorrheal prostatitis,²⁷ gonorrheal salpingitis,²⁸ gonorrheal urethritis,²⁷ pelvic inflammatory disease,²⁰ "hepatic infections,"²¹ Hodgkin's disease,¹² infectious arthritis,³⁰ interstitial keratitis,³¹ iritis (subacute),³² multiple sclerosis,³³ mycosis fungoides,³⁴ optic atrophy,¹¹ osteogenic sarcoma,³⁵ osteomyelitis,¹⁷ Parkinson's syndrome,³⁰ peripheral vascular disease,³⁷ psoriasis,³⁸ psychoses,³⁰ pyelitis,⁴⁰ radiculitis,¹¹ Raynaud's disease,¹¹ rheumatic fever,¹⁰ sciatic neuritis,¹⁰ scleroderma,⁴¹ septicemia (staphylococcal),¹⁷ syphilis,⁴² syphilitic meningitis,¹¹ ocular syphilis,⁴³ syphilis of the nervous system,⁴⁴

trichinosis,⁴⁵ tuberculosis,⁴⁶ tumors⁴⁷ and undulant fever⁴⁸

I wish to emphasize most strongly that it is probable that fever therapy is of little or no value in the treatment of a number of these diseases and that in some diseases mentioned it is distinctly dangerous to attempt fever therapy. Studies during the past year have added to our information concerning the use of artificial fever in some diseases.

Subacute Bacterial Endocarditis (Endocarditis Lenta)—Studies⁴⁹ have demonstrated very definitely that, although there was apparently some slight temporary relief of pain and lowering of temperature following artificial fever therapy, no permanent beneficial effects were noted in any case. Because of the presence of soft vegetations on the endocardium, the very marked increase in blood velocity produced by fever therapy apparently increases the danger of embolism. Either cerebral embolism or generalized embolism may occur. Freund and Watts⁴⁹ have demonstrated definitely that *Streptococcus viridans* can resist the very highest temperature that the human body can tolerate. These results constitute a warning to abandon any further attempt to use fever therapy in subacute bacterial endocarditis.

Bronchial Asthma—Studies⁵⁰ indicate that in a total of at least 117 cases the results were favorable in 104 cases, unfavorable in ten cases and slight or indifferent in at least three other cases. These results would seem to indicate that well equipped hospital fever therapy departments are justified in continuing to administer fever therapy to patients who have intractable bronchial asthma which has failed to respond to all other means of treatment. However, the beneficial results are frequently merely temporary and in some instances no improvement can be expected. Because of the severity of the treatment, fever therapy should not be attempted unless all other means have failed. In no instance should fever therapy be attempted as an office procedure.

Chorea—Reports⁵¹ indicate that, of approximately thirty patients, eight have been classed as "cured," seven as markedly improved, eleven as improved, none as unimproved, and in four or more cases the results have not been reported. The total number of such cases is too small for one to draw any final conclusions. It would seem that none but well equipped institutions which are conducting studies on the effects of artificial fever therapy should attempt to use this method of treatment until further studies have been presented.

Gonococcal Infections—Studies⁵² indicate that in 187 cases of gonorrhea approximately 121 patients

were clinically "cured" and twenty-eight were improved. In four cases results were not reported. These figures seem to be startlingly good. Despite the severity of this type of treatment, its use by properly organized teams of workers in well equipped institutions seems justified in cases in which there is no contraindication to fever therapy.

Gonorrheal Arthritis—Studies⁵³ reveal that, with one exception, all investigators reported startlingly good results in the treatment of gonorrheal arthritis with artificial fever by physical means. These early reports reveal that after treatment with artificial fever 70 per cent of the patients who had gonorrheal arthritis were symptom free, an additional 10 per cent were markedly relieved, and the other 20 per cent were unimproved. The studies indicate that the earlier in the course of the arthritis the treatment is given the greater is the opportunity for complete subsidence of the infection and for nearly complete restoration of articular function.

Gonorrheal Complications Other Than Arthritis—Studies on gonorrheal corneal ulcer,⁵⁴ gonorrheal endocervicitis,⁵⁵ gonorrheal prostatitis,⁵⁶ gonorrheal salpingitis⁵⁵ and gonorrheal pelvic inflammatory disease⁵⁸ indicate that if proper technic is employed these complications will respond favorably to prolonged, high artificial fevers.

Infectious Arthritis—The work of various investigators⁵⁷ shows that about 30 per cent of the patients with infectious arthritis who were treated with artificial fever were significantly improved and that about 70 per cent showed little if any improvement.

Multiple Sclerosis—Several investigators⁵⁸ reported the treatment of this condition with induced fever. The results were for the most part unfavorable but the number of cases reported is insufficient to permit the drawing of any final conclusions.

Mycosis Fungoides—Reports⁵⁹ signify that, in ten cases of mycosis fungoides in which artificial fever therapy was employed, moderate and temporary improvement was noted in eight. In one case the treatment had to be discontinued because of an intercurrent, severe herpes zoster, and in another case the treatment was "of no avail."

Parkinson's Syndrome—Hefke⁴⁰ and Rogers¹¹ reported the treatment of this condition with fever therapy, and Schmidt⁶⁰ had previously advocated fever therapy for the treatment of the postencephalitic type of this syndrome. It would probably be best to heed the statement of Riesman,⁶¹ namely, that "fever therapy in the form of diathermy or malarial or bacterial injections seems to produce no permanent benefit. It may even do harm."

Syphilis (Early)—Studies⁶² indicate that artificial fever therapy combined with chemotherapy affords better results than can be obtained with the use of either one alone. Simpson⁷⁰ advocates the use of fever therapy in the treatment of primary syphilis as well as in the later stages. In a recent article, Neymann and others⁶³ have discussed pertinently the value of artificial fever by physical means. In the late stages of syphilis most of the studies have been made on the usefulness of fever therapy in the treatment of syphilis of the nervous system and in the treatment of ocular syphilis.

Ocular Syphilis—Studies⁴³ indicate that the combined fever-chemotherapy technique of Simpson is of considerable value in the treatment of some forms of ocular syphilis, particularly interstitial keratitis, syphilitic exudative uveitis and choroiditis.

Syphilis of the Nervous System—Reports⁶³ indicate that fever produced by physical means may be used successfully in the treatment of dementia paralytica, tabes dorsalis and other forms of syphilis of the central nervous system. The studies suggest that physical methods of creating fever produce results somewhat comparable to those obtained with malarial therapy. The data, however, are still insufficient to permit one to draw final conclusions.

Tuberculosis—Investigations⁶⁴ indicate that artificial fever should be employed with the greatest of care even in experimental studies. There is great danger of doing injury to the patient if fever therapy is used in this disease and the study of this phase of treatment of tuberculosis should, for the present, remain entirely in the hands of research groups.

Undulant Fever—Prickman and Popp⁶⁵ have noted rather striking response to fever therapy in three patients who had undulant fever. I have recently treated a fourth patient who has shown a sudden and very spectacular remission of the chills and fever following three sessions of high fever artificially produced. The number of patients is insufficient for one to draw any final conclusions with regard to this disease.

Conclusions with Regard to Diseases Treated—The studies which have been made during the last year indicate that the chief sphere of usefulness of this form of therapy lies in the treatment of gonorrhea, both acute and chronic, and its complications. It would appear that it may be of value in the treatment of syphilis in its various manifestations, particularly when fever therapy is combined with chemotherapy. While there is a suggestion that artificial fever produced by physical means may be helpful in the treatment of intractable bronchial asthma in selected cases of chronic infectious arthritis, chorea and undulant fever, nevertheless clinical data are not sufficient to permit any final conclusions. Its value in about forty other dis-

eases remains to be proved. It seems to offer promise of considerable usefulness as a therapeutic agent particularly in the treatment of gonorrhea.

EFFECTS

A summary of the numerous studies on the effects of fever produced by physical means indicates that the following changes are produced.

Bactericidal Effects—*Neisseria gonorrhoeae* generally is destroyed at a temperature of from 106 to 107 F in from six to twenty-seven hours.⁶⁶ In a high percentage of cases of syphilis, darkfield illumination will fail to reveal the presence of *Spirochaeta pallida* after the patient has been treated with fever induced by physical means.⁶ Following exposure to temperatures within physiologic ranges, no cultural changes, in vitro, are noted in *Mycobacterium tuberculosis*, *Streptococcus haemolyticus* or *Streptococcus mitis*.⁶⁷ The last named organism appears to resist, in vivo, any degree of heat possible for the human body to tolerate.⁴⁹ *Micrococcus catarrhalis*, *Haemophilus conjunctivitis*, *Haemophilus influenzae*, *Brucella abortus*, *Escherichia coli*, *Eberthella typhosa*, *Streptococcus haemolyticus*, *Streptococcus viridans* and *Diplococcus pneumoniae* (type 1 and type 3) usually resist in vitro temperatures of 107 F for a period of twenty-four hours, an occasional strain shows some reduction in numbers.⁶⁸

Effects on Circulatory System—The pulse rate and circulatory rate are increased.⁶⁹ The minute volume output of the heart is increased and the velocity of the blood may be increased as much as 400 per cent.⁷⁰ There is an initial increase followed by a decrease in the blood pressure and a decrease in pulse pressure.¹² There is a marked increase in the pulse volume changes of the fingers in all types of artificial fever, with the exception of fevers caused by foreign protein. It has been suggested that the vasodilatation which occurs during fever produced by foreign protein is possibly of central origin, while the vasodilatation which occurs in artificial fever induced by external heat with a consequent prevention of heat loss is chiefly of peripheral origin. The maximum increase of circulation in artificial fever occurred in general at temperatures between 103 and 104 F.⁴ Alterations in the electrocardiogram are not uniform. While the amplitude of the contractions is decreased, it cannot be inferred that fever therapy has any harmful effect on the heart.⁷¹ There is no change in the volume, or only a slight concentration of the blood, and no change occurs in the viscosity of the blood when the intake of fluids is encouraged.⁷² The visible capillaries of the nail beds are increased in number and size. The erythrocyte count generally is not changed.⁷² An initial decrease and a subsequent increase occur in the number of

leukocytes⁷² There is a relative and an absolute decrease in the number of lymphocytes⁷³ The hematopoietic response is characterized by consistent leukocytosis, with delivery of polymorphonuclear neutrophils of increasing immaturity Destruction of lymphocytes occurs and there is probably some destruction or redistribution of monocytes A shift of the neutrophilic granulocytes to the left and the presence of clasmato-cytes in the peripheral blood (which are outstanding in malaria) are not seen in cases in which fever is produced by physical means⁷⁴

There is no change in the nitrogenous constituents (urea, uric acid, creatinine) or there may be slight increase (if there is an increase in the concentration of the blood)⁷⁵ There is nearly consistent increase in the creatinine clearance, in contrast to wide variations which occur in infections⁷⁶ There is no change in the nonnitrogenous constituents (sugar, phosphorus lipids, calcium) or only a slight increase (if there is an increase in the concentration of the blood)⁷⁷ No significant decrease occurs in the lipids of the plasma, such as is seen in acute infections⁷⁸ There probably is an alteration in the acid-base balance of blood in the direction of slight alkalosis⁷⁹ Marked alkalosis may be noted⁸⁰ Opinions vary as to the effect on the chlorides, some writers say that there may be marked decrease,⁸¹ while others say that there is no significant change⁸² If salt or weak saline solution is administered by mouth during treatment, the blood chlorides drop very little If no sodium chloride is administered and sweating is profuse, a drop in the blood chlorides is to be expected The oxygen content and oxygen combining power of venous blood are increased⁸³ Opinions also vary as to the effect on the agglutinins, but the agglutination titer generally is within normal limits⁸⁴ The complement fixing antibodies are temporarily diminished, but there is no change in the opsonic index⁸⁵

Other Effects—Examination of the gastric contents reveals a sudden decrease in the amount of chlorides and an increase in the amount of lactic acid⁸⁶ The urine is increased in amount but temporary oliguria generally occurs⁸⁷ The reaction of the urine is unchanged, or the urine is slightly alkaline and its specific gravity is increased⁸⁸ The basal metabolic rate is increased approximately 7 per cent for each degree of fever induced⁸⁹ Cold fluids, taken by mouth, produce fluctuations in the gastric temperature but do not appreciably affect the general temperature⁹⁰ Comparison of temperatures in the median antibrachial vein, rectum uterine cervix, Hunter's canal, bladder

and spinal canal indicate that records of the rectal temperature provide an accurate index of the temperature of the deep tissues⁹¹ After each individual treatment there may be a temporary loss of weight due to loss of fluid (unless sufficient fluids are taken by mouth) However, this loss is quickly regained and, after a course of fever therapy, a patient usually retains his original weight or even gains weight

PATHOLOGIC CHANGES

Hemorrhagic encephalitis has occurred in some instances, and hemorrhagic pneumonia also has been noted Deterioration and hemorrhage may occur in the cortex of the adrenal glands Death may occur as the result of vascular collapse Since both fever therapy and sodium amytal (which is frequently used as a sedative in fever therapy) tend to produce marked dilatation and engorgement of the blood vessels, it is suggested that the combination should not be used⁹² In tuberculous animals, marked hemorrhages may occur in tuberculous lesions Tuberculous lesions are more extensive among animals that have been treated with induced fever than they are among animals that have been used as controls⁹³ In subacute bacterial endocarditis there is apparently danger that fever therapy may produce multiple emboli⁹⁴

TECHNIC

Studies during the past year have emphasized the facts previously stressed by the Council on Physical Therapy, namely, that production of fever by physical means is strictly a hospital procedure, that it is essential that a well trained personnel be in complete charge of the work, that skilful nurse technicians, who have had at least one month's supervised training, administer the treatments, and that a physician be in constant attendance Patients to be treated with fever should be selected with as much care as are patients who are to undergo a major surgical operation

The dangers that have been mentioned—of emboli hemorrhages and sudden death—are extremely rare when the administration of the fever treatments is in the hands of a competent, well organized group However, there is certain to be a very slight mortality with a treatment as heroic as this If these treatments are given without proper control or are considered as simple office procedures, there is danger of harm to the patient or even death

Opinions vary as to the best and safest physical means of producing fever Almost any one of the methods described in this article may be used with the confidence that it will produce favorable results provided the team of workers who are using it have developed a good technic for the particular method

It would seem quite apparent that, for the present the medical profession as a whole should avoid the use of fever therapy unless there is available an institution properly equipped to administer this type of treatment

The controversy still goes on concerning the effectiveness of fever produced by physical means as compared to fever produced by malarial inoculations or by injections of foreign protein It is not the purpose of this article to enter into this controversial phase of the subject It would seem from a clinical standpoint that the production of artificial fever by physical means offers certain factors of control and safety which make it appear preferable in some instances to the production

of fever by malarial inoculations or by injections of foreign protein. Likewise, clinical observations would indicate that in the treatment of disease by these two methods the results obtained are somewhat comparable.

COLLINS VASCULATOR ACCEPTABLE

Manufacturer: Warren E. Collins, Inc., Boston

The Collins Vasculator, according to the manufacturer, provides a convenient means of applying alternate suction and pressure in the treatment of peripheral vascular disease. The essential parts of this device are the pump, the motor, and the boot or chamber.

A rotary pump supplies both positive and negative pressures and is driven by a V-belt connected to a one-quarter horse power electric motor, which is supplied for either alternating or direct current. A valve, operated by a cam alternatively connects the suction and pressure outlets of the pump to an air duct leading to outlets at the rear of the cabinet. The cam which establishes the timing of the pressure changes is driven by a reduction gear connected to the pump shaft by a V-belt, and makes one revolution in approximately thirty seconds. The cam operates a lever which cruses the valve to connect the air duct to the suction side of the pump for approximately twenty-five seconds and to the pressure side for five seconds. Other combinations are available.

Connected to the air duct is the pressure indicating gage which is mounted on the front of the cabinet. The gage is calibrated in millimeters of mercury and indicates accurately both suction and pressure.

Also connected to the duct are two control valves, one of which regulates the pressure, the other the suction. Each valve is provided with spring tension varied by a screw to which the control knob is attached. A stop on the adjusting screw limits the amount of tension applied to the spring and, accordingly, the maximum amount of suction or pressure in the air duct, outlet manifold, and treatment chamber. These valves therefore perform the function of conventional safety valves," as well as regulating the pressures.

The mechanism is assembled on a steel chassis which is mounted in the cabinet on rubber mountings, to minimize the transmission of vibration and mechanical noise. The Vasculator cabinet is made of steel, with hinged cover which affords access to the control valves and also the mechanism. The cabinet is 30 inches high, 26 inches wide and 15 inches deep and is mounted on rubber-tired ball bearing casters. The interior is lined with sound absorbing material.

The treatment chamber or boot is constructed of steel and is approximately 30 inches long, 14 inches high and 12 inches wide. The upper half is provided with a window of heavy-gauge cellulose acetate. At one end is an opening through which the leg or arm to be treated is inserted. The opening is rendered air tight during treatment by means of rubber cuffs mounted on aluminum rings, which are clamped to the end of the boot. The cuffs are supplied in a total of eight graduated sizes ranging from

Collins Vasculator

3½ inches to 7 inches in diameter. The mounting ring for each cuff is marked with the circumference of the cuff, enabling fitting by measuring the arm or leg with a tape measure at the point where the cuff is to be applied.

The Vasculator is provided with outlets for the operation of two boots. These are connected to the apparatus by rubber hose, tapered outlets being provided for its attachment.

The motor requires an electrical input of between 300 and 400 watts, depending on the load, which varies somewhat with the individual pressure variations as well as with the pressure adjustment.

Some indications for the use of this type of apparatus appear to be acute vascular occlusion, freezing, and vascular diseases with major involvement of the large vessels. Contraindications appear to be thrombophlebitis, cellulitis or lymphangitis (acute

or subacute) extensive destruction of the arteriolar or capillary vessels, advanced thrombo-angitis obliterans with capillary stasis and advanced arteriosclerosis with capillary stasis, and venous thrombosis.

This apparatus has a very limited field of usefulness and probably therefore does not belong in the armamentarium of the average physician. It belongs rather in the realm of hospital equipment, since most of these rare arterial diseases are hospital cases.

In view of the satisfactory performance of this unit with reference to the treatment of acute vascular occlusion, freezing and vascular diseases with major involvement of the large vessels, the Council on Physical Therapy voted to include the Collins Vasculator in its list of accepted apparatus.

Council on Pharmacy and Chemistry

REPORTS OF THE COUNCIL

Nomenclature of Endocrine Principles III

THE PRESENT UNSETTLED STATE OF ENDOCRINOLOGIC NOMENCLATURE HAS BEEN THE CAUSE OF INCREASING CONFUSION IN RECENT YEARS. IN AN EFFORT TO REMEDY THIS DEPLORABLE SITUATION THE COUNCIL SOLICITED THE COOPERATION OF A NUMBER OF EXPERTS WHO HAVE MADE FUNDAMENTAL CONTRIBUTIONS TO GLANDULAR PHYSIOLOGY. THIS GROUP TERMED THE ADVISORY COMMITTEE ON THE NOMENCLATURE OF ENDOCRINE PRINCIPLES IS COMPOSED OF THE FOLLOWING: DR. EDGAR ALLEN, WILLARD M. ALLEN, J. B. COLLIP, G. W. CORNER, E. A. DOISY, E. T. ENGLE, H. M. EVANS, R. T. FRANK, F. L. HISAW, F. C. KOCH, LEO LOEB, G. F. MARRIAN, C. R. MOORE, OSCAR RIDDLE, P. E. SMITH, AND C. W. TURNER. M. S. BISKIND, CORRESPONDING SECRETARY. ON THE RECOMMENDATION OF THIS COMMITTEE THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT WHICH IS THE THIRD OF A SERIES. THE PRECEDING REPORTS APPEARED IN THE JOURNAL MAY 23, 1936, PAGE 1808, AND JULY 18, 1936, PAGE 210. IT IS ANTICIPATED THAT ANOTHER REPORT ON A RELATED TOPIC WILL BE PUBLISHED IN THE NEAR FUTURE.

THE COUNCIL DESIRES TO EXPRESS ITS SINCERE APPRECIATION TO THE MEMBERS OF THE ADVISORY COMMITTEE FOR THEIR WILLING COOPERATION.

PAUL NICHOLAS LEECH, Secretary

THE NOMENCLATURE OF ESTRUS-PRODUCING COMPOUNDS

Crude extracts of ovary and placenta which produced uterine growth were obtained by Adler¹ (1912), Iscovesco² (1912), Fellner³ (1912), Herrmann⁴ (1915) and others. Using a similar biologic reaction, Robert Frank⁵ (1922) made the significant discovery that liquor folliculi also contains an active substance. However, the chemical work leading to purification and isolation did not progress rapidly, owing primarily to the difficulties of assay, but with the introduction of Allen's rapid vaginal smear method (Allen and Doisy,⁶ 1923) based on the phenomenon described by Stockard and Papanicolaou, investigation of the follicular hormone became very active. Among the subsequent contributions leading to the isolation of pure crystalline estrogenic compounds, the discovery of Aschheim and Zondek⁷ (1927) of the estrus-producing property of the urine of pregnant women was, perhaps, the most important.

The first crystalline estrogenic compound was isolated by Doisy, Veler and Thayer⁸ in 1929, shortly after this discovery was announced. Butenandt⁹ (1929) reported the isolation of

the same compound. In the following year Marrian¹⁰ (1930) obtained a different estrogenic compound in the crystalline condition shortly thereafter, Doisy and his co-workers¹¹ (1930) reported the isolation of the same compound. In 1932 Girard and his collaborators¹² reported the isolation of three additional crystalline compounds and Butenandt and Störmer,¹³ and Schwenk and Hildebrandt¹⁴ claimed the isolation of two isomers of the compound originally isolated by Doisy. Using tissues instead of pregnancy urine, Browne and Collip¹⁵ (1931) isolated the compound originally obtained by Marrian. In 1935 MacCorquodale, Thayer and Doisy¹⁶ reported the separation of still another pure estrogenic substance from hog ovaries, and Wintersteiner, Schwenk and Whitman¹⁷ obtained the same compound and one of its isomers from the urine of pregnant mares. Thus there are at least seven naturally occurring estrogenic substances that have been isolated in a crystalline condition. As the result of investigations by Butenandt, Cook, Doisy, Marrian and their respective associates the structure of these and related compounds has been definitely established.

In their earlier work Allen and Doisy called the active substance of liquor folliculi the ovarian hormone, but with the proof of the existence of another ovarian hormone (Hisaw,¹⁸ 1928 Corner,¹⁹ 1929) they changed their designation to ovarian follicular hormone.²⁰ In spite of their realization that this term was cumbersome, they expressed the view that investigators should await the actual isolation of the hormone before applying a name. However, others, chiefly pharmaceutical houses, did not hesitate to apply names. As a few examples, some English investigators called the follicular hormone oestrin, Parke, Davis and Company named its commercial product estrogen, Laqueur called his extract menformon, Loewe, thylinin, and Zondek, folliculin. The term oestrin^{20a} came into rather widespread usage particularly in England.

20 In the historical development of our knowledge of the regulation of the sexual cycle the following periods may be distinguished. 1 Not only did Frankel attribute to the corpus luteum the function of making possible and maintaining pregnancy but he considered this organ also as the active agent in the ovary. 2 The experiments of Loeb defined the principal functions of the corpus luteum. These made it evident that other factors entered into the domination of the cyclic functions besides the corpus luteum. All the available evidence pointed to the large and mature follicles as the additional factors. These investigations led to the development by Loeb of the concept that a follicular phase and luteal phase have to be distinguished in the sexual cycle. 3 The experiments of Frank and especially of Edgar Allen and Doisy very clearly proved the existence of the follicular hormone. This led to the isolation of pure estrogenic compounds by Doisy and by Butenandt. 4 The comparative evidence in favor of the existence of the two phases mentioned was given especially by Corner and Parkes. 5 The work of Corner and Allen as well as of Hixon initiated the investigations which led to the purification of the corpus luteum hormone. The significance of the corpus luteum in regulation of the growth of the mammary gland was proved or

4 by Turner.

20a The use of the term (o)estrin as a generic name has caused much confusion (see *Glandular Physiology and Therapy* Chicago American Medical Association, 1935 page 477). The almost identical designation "estern" is a registered trade mark under which Frederick Stearns and Company markets a mixture of acetylsalicylic acid, acetophenetidin and caffeine.

With the isolation of the first crystalline estrogenic substance, Doisy sought advice from the Council on Pharmacy and Chemistry on a name for the new compound. It was obvious that the name to be selected should avoid confusion with existing commercial names and also with names for impure extracts. The name selected was theelin (Veler, Thayer and Doisy, 1930). Since there was no established international agency for nomenclature, this term was submitted to the Council on Pharmacy and Chemistry, which approved it as the common name on the condition that it be neither patented, copyrighted nor trademarked. This condition was met and according to Doisy has been adhered to.²²

However, the term theelin has not been widely accepted. Marrian retained the name oestrin and on recognition of several oestrogens used distinctive modifications of the original term, Butenandt has used the terms progynon or follikelhormon, Laqueur, menformon (cryst), and Browne and Collip, emmennin, for their crystalline compounds. Perhaps the reasons why the name theelin did not gain universal recognition were that (1) Parke, Davis and Company was allowed to market its preparation of the crystalline substance under the name theelin, (2) the suffix "in" is not indicative of the chemical nature of the compound, (3) no system of nomenclature for compounds of this series has been proposed.

Two systems of nomenclature have been proposed, one by Girard²³ using the root "folli-" with suffixes to indicate the nature of the compounds the other by a group of English investigators (Adam and collaborators²⁴) using the root "oesir" with certain modifications. It is not known whether, in either case, other investigators were consulted.

In view of the importance of Edgar Allen's investigations in opening up the field of the follicular hormone and of Doisy's contributions in isolating the first crystalline estrus producing compound and the further fact that the Council has approved theelin as a common name, the Advisory Committee considered a proposal (1) to retain "theel-"²⁵ as the root for the names of the estrus-producing compounds, (2) to adopt a system of suffixes in accordance with recognized principles of nomenclature which would provide satisfactory common names for the entire group of known compounds and of compounds which may be isolated in the future, (3) to modify the designation of the substance now known as theelin in order to remove the objections resulting from its trade usage

However, in view of the fact that the system of nomenclature devised by Adam and his collaborators²¹ has been fairly widely adopted among investigators, it appeared inadvisable to supplant this system even though the new system based on "theel" was simpler and more nearly in accord with the nomenclature for the androgens. But, as theelin¹ was the name applied by the discoverers of the first crystalline estrogenic compound and

21 Veler C. D Thayer S A and Doisy E A The Preparation of the Crystalline Follicular Ovarian Hormone Theelin J Biol Chem. 87: 357 (June) 1930

22 In New and Nonofficial Remedies 1936 page 323 the following statement occurs "The Council has recognized the nonproprietary name Theelin for the crystalline (ketohydroxy) estrogenic hormone as described by Doisy and the nonproprietary name Theolol for the crystalline (tri-hydroxy) estrogenic hormone as described by Doisy. The adoption of these names as nonproprietary designations was based on an agreement with E. A. Doisy that the name [theelin] will not be copyrighted or used as a trademark. Furthermore the contract of St. Louis University with its licensee Parke Davis & Co. requires that the name must be submitted for approval to the Council. In presenting theelin to the Council in 1931 Parke Davis & Co. specifically stated that theelin was not a trade mark and had not been registered in foreign countries. Neither 'theelin' nor 'theolol' appears in the list of names registered with the Pharmaceutical Trade Mark Bureau (1934) this list contains both names that are registered trade marks and others which are not registered in the patent office."

"Theelin and theelool do appear in appendix XIV of the British Pharmacopoeial Codex 1934 entitled Substances with Proprietary Trade Names. This has been cited as evidence that these names are in fact proprietary. However in the introduction to this appendix it is stated that it is important to note that the majority of names included in the list are registered trade-marks and unprotected names. It is obvious that the list between trade marks and unprotected names is such that the term 'unprotected' designations being in the latter category and that the term 'unprotected' is being loosely employed in the Codex. In an official British publication The Extra Pharmacopoeia of Martindale and Westcott 'theelin is indicated as a nonproprietary designation. 'Theelin and 'theelool appear in fact therefore to be non-proprietary names."

Estratriene	 $C_{15}H_{24}$	Δ^1 -Estratriene	Equilenin	 $C_{15}H_{18}O_2$	3 hydroxy, 17 keto Δ^1 -estra- pentaene
Estrone or Theelin	 $C_{15}H_{22}O_2$	3 hydroxy, 17 keto Δ^1 -estratriene			

clature based on the root *estr-*, (2) to retain *theelin*, *theclol* and *dihydrotheelin* as synonyms for the compounds known in the aforementioned system as *estrone*²⁶, *estriol*²⁷ and *estradiol*

²⁶ The term *estrone* had been registered by Parke, Davis and Company with the Pharmaceutical Trade Mark Bureau²⁵ but according to the firm it was not registered in the U. S. Patent Office. On the request of the Secretary of the Council, Parke, Davis and Company has agreed to relinquish any proprietary rights that it may have in this name.

²⁷ The name *estriol* (which might readily be confused with *estriol*) is a registered trade mark which is owned by Frederick Stearns and Company and under which it has marketed its preparation of benzyl succinate. This firm in response to a request by the Secretary of the

common and chemical names of the estrogens are given in the accompanying table.

Council has commendably agreed to relinquish proprietary rights in the trade mark *estriol* in order to avert possible confusion. The Council desires to express its appreciation to Frederick Stearns and Company for its cooperation in this matter.

²⁸ *Estrogen* is a registered trade mark belonging to Parke, Davis and Company. On the request of the Secretary of the Council this firm has commendably agreed to relinquish its proprietary rights in the name on its adoption by the Council as a generic term. The Council desires to express its appreciation to Parke, Davis and Company for its action in this matter as well as in the case of the name *estrone*.

CHILD MORTALITY FROM AUTOMOBILE ACCIDENTS

In every section of the country, concentrated efforts by towns and cities have developed toward diminishing the number of automobile accidents and fatalities. The statistics that have been compiled give evidence of the appalling automobile mortality each year. There is little reason to believe that these figures will diminish in magnitude in the near future. Rigorous measures are required to remedy the condition and to limit the number of accidents. Direct emphasis of the importance of necessary restrictions can best be obtained by a program of public education, based on a compilation and analysis of detailed statistics bearing on the subject. The material dealing with automobile fatalities usually refers only to the total number of lives lost during some definite time in the entire country or in some selected area and only occasionally deals with the loss of life suffered in broad age groups. Careful treatment of mortality figures in various age groups in different geographic regions are of considerable value in bringing proper stress on the seriousness of the situation and in serving as excellent support for proposed programs of reform designed to remedy the condition. This is particularly true for statistics dealing with mortality among children, because of the more marked sentimental appeal that can be made on this basis. Adequate surveys of child mortality from automobile accidents are therefore of particular significance and the United States Public Health Service is rendering valuable aid in supplying these data.

The first two reports in a series of studies on the fatal accidents of childhood have just been compiled by W. M. Gafaer,¹ senior statistician of the United States Public Health Service. The first report considers child mortality in different geographic regions of the United States and deals with single years of age under 5 and for the age groups 5 through 9 and 10 through 14 years. In this report the period is limited to 1930 principally because it is the most recent year for which

accurate population enumerations exist. The second report presents a study of certain time changes in the distribution of mortality from automobile accidents among children in the United States. The period in this publication extends from 1925 through 1932. For purposes of comparison of automobile fatalities with other causes of death, statistics are included for mortality from other accidents, and for further comparative purposes the mortality is included from three common communicable diseases, namely, measles, scarlet fever and diphtheria. Analysis of these comparative data reveals that under 15 years of age there were more than two deaths from accidents to one death from the three diseases, only for infants of 1 year is the ratio less than 1. Mortality from automobile accidents seems to vary in importance with age. Considering all total accidents, mechanical suffocation leads at under 1 year of age, burns at 1 and 2 years, automobile accidents and burns at 3, and automobile accidents at 4, 5 to 9 and 10 to 14 years of age. Of forty-seven states and the District of Columbia, divided into four broad geographic groups the Northeastern section of the country leads in deaths of children from automobile accidents, this is undoubtedly related to the comparatively large number of automobile registrations in this area.

These illuminating statistics present interesting relationships between the number of fatalities from automobile accidents and those from accidents of all types and strikingly emphasize the overwhelmingly high mortality of children from automobile accidents. Such a survey should serve as a concrete basis not only for drastic and sane restrictions on the operators of motor vehicles but also for emphasizing to the pedestrian the potential danger of the automobile.

THE SEX RATIO AT BIRTH

Various theories have been offered in explanation of the well known fact that the number of male births always exceeds that of female births. Although the biologic processes that ultimately determine the preponderance of males as compared with females at birth are, according to Russell,¹ imperfectly understood yet, it is possible to study the relation to such purely external factors as age, nationality and social status of the parents, and to primogeniture and size of the family, seasonal and secular trend, and the extent to which it is influenced by cross-breeding, migration and social upheavals. Such was the purpose of the study recently reported by Russell.

The statistics on which the investigations were based were obtained from (1) the Annual Reports of the Registrar-General for England and Wales, (2) the Reports on Births and Still Births in the United States, (3) *Annuaire international de statistique* and (4) the

¹ Gafaer, W. M. *Pub. Health Rev.* 51: 1093 (Aug. 7) 1936 (Aug. 28) 1936.

¹ Russell, W. T. *Statistical Study of the Sex Ratio* - 1935. *J. Her.* 36: 381 (July) 1937.

records of families given in Burke's Peerage for the seventeenth, eighteenth and nineteenth centuries. In England and Wales the proportion of males per thousand females during the past ninety-five years ranges from 1,032 to 1,061, the latter value occurring immediately after the war. The mean ratio over the whole period was 1,043, and the average dispersion or scatter as represented by the standard deviation was 5.7. For London the experience over a longer series of years (292, from 1629 to 1920) could be obtained from the study of christenings. Since there is no evidence of the selection of christening of boys as compared with girls, the resultant figures cannot be considered inaccurate per se. The values obtained correspond closely with those for England and Wales for a shorter period.

The association between the degree of urbanization and the size of the sex ratio has concerned some writers on the subject. The evidence obtained from English data with regard to the higher proportion of masculinity in the rural areas as compared with urbanized centers is supported by the available statistics in the United States. The latter showed that the sex ratios in the urban and rural areas during the period 1927-1929 were $1,057 \pm 1.20$ and $1,064 \pm 1.15$ respectively. The difference of 7 ± 1.66 in favor of the rural areas is thus greater than would be expected to arise by mere chance. A possible explanation of the higher ratios of live births in rural areas as compared with urban centers is a probable lower incidence of abortions in the former, superadded to the undoubted fact that the proportion of still births to total live births is lower in the country than in the town. Some investigators have stressed the fact that the sex ratio of illegitimate births is smaller than that of live births. The English statistics, however, reveal an index for illegitimate births almost identical with that for legitimate ones.

A study of the seasonal variation of the index in England and Wales supports the general belief in the absence of any seasonal correlation. However, the statistics for the urban and rural divisions of the United States for the period 1921-1924 and for New York City for 1929-1933 reveal evidence of a definite trend. In each area the sex ratio is lowest in the first quarter, attains its maximum in the second, and then gradually declines, hence the American statistics, contrary to the experience in England, support the view that conception occurring from July to September is favorable to increased masculinity.

In some countries, particularly Greece, the masculinity of births is exceptionally high, in others, Japan and Italy, low, and there is evidence that the ratio may be influenced through such a factor as migration. Births resulting from marriages of the same nationalities in foreign lands result in a lower sex ratio than those occurring in the home land. There is no satisfactory evidence obtainable that marriage of different nationals, or what may be termed crossbreeding,

influences the index. Social upheavals do influence the index. In countries that were affected by the World War, the sex ratio was high. It was higher after the termination than during the war. Neutral countries experienced the same phenomenon but not to such an appreciable degree. The ratio is higher among first born children and declines with increased family size. In England and Wales the masculinity ratio is definitely correlated with social status, i. e., the index decreases in size with descent in the social scale. The causes for this are not clear.

Russell was able to find no conclusive evidence that the sex ratio is related to the age of the parents, but any relationship that may exist is with the age of the father rather than with the age of the mother. The biologic fact of the preponderance of male births in the human race is an established one but its purpose is still a matter of debate.

The observations brought out by the studies of Russell and others furnish material of wide interest to all those interested in biologic processes. A further analysis of the factors that may be involved would doubtless prove of additional significance. The sex ratio in other species of animals might serve as the essential clue in determining the ultimate objectives of nature in producing this inequality.

VITAMIN C AND TUBERCULOSIS

Investigations during the past few years have indicated that vitamin C plays an important part in determining the resistance of the animal organism to certain types of bacterial infections and toxins. For example, guinea-pigs fed a ration deficient in the vitamin are much less resistant to diphtheria toxin than are normal control animals, similarly, the administration of vitamin C (cevitamic acid) to normal guinea-pigs increases their resistance to the toxin¹. A protective effect of vitamin C against tuberculous infections in animals has likewise been described repeatedly. Decreased resistance to tuberculous infection develops in animals fed a vitamin C deficient diet and, conversely, an increased susceptibility to acute scurvy is seen in infected animals.

The comparatively recent introduction of methods for the determination of vitamin C and for following the intake and excretion of the vitamin has made possible studies on the metabolism of this substance in human subjects. As a result, the amounts of vitamin C ingested daily in the ordinary mixed diet and excreted daily in the urine of normal human subjects are known with some degree of certainty. More recently, studies of this type have been made on patients with various diseases, the results in tuberculous patients have been

1 Greenwald C. K. and Harde E. Vitamin C and Diphtheria Toxin. *Proc Soc Exper Biol & Med* 32:1157 (April) 1935. King C. G. and Menten M. L. The Influence of Vitamin C Level upon Resistance to Diphtheria Toxin. I. Changes in Body Weight and Duration of Life. *J Nutrition* 10:129 (Aug.) 1935. Juogehint C. W. and Zwemer R. L. Inactivation of Diphtheria Toxin in Vivo and in Vitro by Crystalline Vitamin C. *Proc Soc Exper Biol & Med* 32:1229 (May) 1935.

particularly interesting. Two such studies² have indicated that there is an increased requirement for vitamin C in tuberculosis and that a somewhat subnormal amount of the substance is excreted daily in the urine. A current contribution³ presents further data of this type obtained on a group of forty-four patients with mild, moderately advanced or far advanced tuberculosis. The amount of vitamin C excreted daily in the urine was determined by titration against 2,6-dichlorophenyl-indophenol and the values obtained were classified into four arbitrary groups in the order of their magnitude. The percentage of patients with active tuberculosis was then calculated for each group, with a rather striking outcome. Five of the six patients in the group excreting the smallest amount of vitamin C, from 0 to 5 mg daily, had active tuberculosis, there was probably some activity also in the sixth. In the second group, which excreted from 5 to 8 mg daily, active tuberculosis was present in nine of fourteen, or 70 per cent, whereas in the group excreting from 8 to 14 mg daily only seven of twenty-one, or 33 per cent, showed activity, and in the group excreting over 14 mg daily only one of thirteen patients, or 7 per cent, showed activity. These results, together with others, seem to indicate that in active tuberculosis there is a decreased excretion of vitamin C or, at least, some substance affecting in a similar manner the method of determining the vitamin. These data may be interpreted as indicating an increased requirement of vitamin C in tuberculosis.

A second type of experiment on the same patients yielded further evidence for an increased vitamin C requirement in tuberculosis. The effect on the urinary excretion of the vitamin resulting from the daily administration of 4 ounces (120 cc) of orange juice containing 55 mg of cevitamic acid was determined. This amount of vitamin C is sufficient to cause a definite increase in the amount excreted by the normal person. As in the preceding experiment, definite differences associated with the degree of activity of the disease were seen in the various patients. In eight of ten cases showing active tuberculosis no increase in vitamin C excretion above a minimal arbitrary value occurred, whereas in all fourteen cases showing inactive tuberculosis a significant increase in the excretion of the vitamin occurred. From these data it appears that between 55 and 138 mg of vitamin C was required daily by patients with active tuberculosis for the maintenance of a normal rate of excretion of the substance. In one patient, 200 mg of cevitamic acid did not suffice for the maintenance of equilibrium between the intake and the excretion of the vitamin. These amounts stand in distinct contrast to the quantity from 15 to 30 mg daily, of vitamin C required by a normal healthy adult.

Although the foregoing evidence appears to indicate definitely the existence of an increased requirement of vitamin C in active tuberculosis, perhaps before final conclusions are drawn several other factors should be considered. The titrimetric procedure for the determination of vitamin C is not entirely specific for cevitamic acid, therefore it would seem that adequate confirmation of the present observations by a different method would be desirable. Also such factors as the possibility of an increase in the excretion of vitamin C through other paths, as the sweat, and possible correlations of the changes in the vitamin requirement in tuberculosis with changes in body temperature should be investigated. In certain diseases, for example, the period of fever appears to be associated with a decreased excretion of vitamin C.

Current Comment

THE PRESIDENT AND SOCIAL SECURITY

Using the occasion of the dedication of the Jersey City Medical Center, President Franklin D. Roosevelt extended appreciation to the medical profession for its services in the depression. He said:

Let me with great sincerity give the praise which is due to the doctors of the nation for all that they have done during the depression, often at great sacrifice, in maintaining the standards of care for the sick and in devoting themselves without reservation to the high ideals of their profession.

This statement had been prefaced by a recognition of the fact that the Public Works Administration had increased the capacity of American hospitals by some 50,000 beds. Moreover, the President mentioned the desire of the medical and nursing professions to do more to help families of small income in time of sickness. Particularly interesting to physicians, however, were the words of assurance in which the President intimated a desire to still certain apprehensions which have been prominent in medical discussions for many months. He continued:

The medical profession can rest assured that the federal administration contemplates no action detrimental to their interests. The action taken in the field of health as shown by the provisions of the splendid social security act recently enacted is clear.

There are four provisions in the social security act which deal with health and these provisions received the support of outstanding doctors during the hearings before the Congress. The American Medical Association, the American Public Health Association and the State and Territorial Health Officers Conference came out in full support of the public health provisions. The American Child Health Association and the Child Welfare League endorsed the maternal and child health provisions.

This in itself assures that the health plans will be carried out in a manner compatible with our traditional social and political institutions. Let me make that point very clear. All states and territories are now cooperating with the public health service. All states except one are cooperating in maternal and child health service, all states but ten in service to crippled children and all states but nine in child welfare.

Public support is behind this program. But let me stress in addition that the act contains every precaution for the continued support and cooperation of the medical profession.

2 Schroeder, Hermann. Die Ausscheidung der Ascorbinsäure im Gesunden und Kranken. *Organismus Klin. Wchnschr.* 14: 484 (April 6) 1935. Bulowa, I. G., Rothstein, I. A., Ratish, H. D., and Harde, E. Cevitamic Acid Excretion in Pneumonia and Some Other Pathologic Conditions. *Proc. Soc. Exper. Biol. & Med.* 34: 1 (Feb.) 1936.
3 Hesse, F. H., and Martin, G. J. Ascorbic Acid Metabolism in Tuberculosis. *Proc. Soc. Exper. Biol. & Med.* 34: 642 (June) 1936.

In the actual administration of the social security act we count on the cooperation in the future as hitherto, of the whole of the medical profession throughout the country. The overwhelming majority of the doctors of the nation want medicine kept out of politics. On occasions in the past, attempts have been made to put medicine into politics. Such attempts have always failed and always will fail.

Government, state and national, will call upon the doctors of the nation for their advice in the days to come.

The meaning of these words should be clear to all who read. They would seem to signify that the voice of organized medicine has been heard and appreciated in the executive branch of our government. They conclude with a promise of consultation with expert medical advice as new problems arise in the future. The devotion of the medical profession to the public need in our years of stress surely warrants such confidence.

Medical Economics

EVILS OF CONTRACT PRACTICE

Contract practice, in this country, was born of geographic and social necessity. When certain pioneering industries such as mining, lumbering and construction work pushed beyond established settlements, such industries were obliged to provide whatever medical facilities were supplied to such isolated communities. This service varied widely in quality but was better than none.

Most modern types of contract practice lack this excuse of necessity. Instead of meeting a lack of facilities in an isolated locality they compete with adequate facilities already established. The motive of establishment is not the benefit of those receiving the service but the possibility of financial gain to those contracting for the delivery of the service. Contract systems are now operated more often to reduce compensation costs, absenteeism, labor turnover, inefficiency and wage payments than to supply needed medical service.

This conclusion as to motive is justified by certain facts. The contract plans do not add to existing services. The features for which their founders fight hardest are those most profitable to industry but not always most helpful to the patients. The managers of the plan insist on choosing the physicians. This choice is determined more by the amounts paid physicians, the character of the medical testimony that will be given in damage suits and compensation cases, and ability to keep down costs than by professional qualifications or devotion to the patient's welfare. The patient is given little or no choice, the most desirable ethical practitioners in the community usually refusing to enter the contract group from which the patient must choose. Contract practice is at present almost universally accompanied by advertising, commercial bargaining, underbidding, subletting, coercion or plain racketeering, and all of these are destructive ingredients in medical service.

If these flagrantly undesirable commercial features could be eliminated, the result of injecting contract practice into the present system of medical practice would still be injurious to the general character of medical service. Contract practice always is restricted to a selected group—generally of adult employees. It leaves uncared for the mass of children, aged women, unemployed and those most in need of medical service. Such an exclusion by reducing the field of private practice, inevitably lowers the quality of care it is possible to give to those outside the contract scheme. By thus lowering the standard of medical service in the field with which contract practice must be compared, this situation tends in turn to lower the standards that will be maintained under contract.

Contract medicine is almost exclusively curative medicine. It gives little attention to prevention. The amount of work demanded of each salaried physician is usually so great that he has little time for immunizations and other preventive mea-

sures. The restricted coverage makes it impossible to reach the children and others most in need of preventive service. The isolated group character of contract practice does not encourage the contract physicians to become interested in preventive work for an entire community.

Contract practice is so prone to a certain set of defects that they may almost be said to be inherent. Insufficient pay to overworked physicians encourages superficial service. When financial considerations such as compensation are dominant, incidents have been recounted in official investigations of unnecessary amputations to insure an earlier discharge and release from compensation payments, and the use of untrained laymen in giving medical care.

Continuous experience through many years in widely separated localities and under most varied conditions would seem to indicate that it is difficult if not impossible to eliminate these undesirable and dangerous features of contract practice. It is too much to expect that commercial interests, having no knowledge of the principles of medical ethics and no understanding or appreciation of the personal and private relationships that should exist between patient and physician, should devise and administer a system of medical care devoted alike to the interests of the public and of the medical profession.

Association News

ABSTRACT OF MINUTES OF MEETINGS OF BOARD OF TRUSTEES

The Board of Trustees held a two-day session at Association Headquarters in Chicago on September 24 and 25.

CHARLES GORDON HEYD, PRESIDENT

On announcement of the death of the President Dr. James Tate Mason, the Board declared Dr. Charles Gordon Heyd President, in accordance with the Constitution and By-Laws of the Association.

APPOINTMENTS

In accord with resolutions adopted by the House of Delegates at the Kansas City session, the Board appointed, or authorized the appointment of committees to study asphyxia, air conditioning, blood grouping, motor vehicle accidents, and the value of x-ray film with paper base as a substitute for film with gelatin base, also an advisory committee on cosmetics. The composition of these committees will be announced later.

Advisory Committee of the Committee on Scientific Exhibit. Dr. Eben J. Carey of Milwaukee to succeed himself for a term of three years, and Dr. James P. Leake of Washington, D. C., to succeed Dr. Hans Zinsser.

Council on Foods. Dr. James S. McLester.

Editorial Advisory Committee for Hygiene. Drs. Olin West, W. W. Bauer, P. A. Teschner, Frank J. Clancy and R. G. Leland.

Representatives on Advisory Committee on Medicine and Public Health of the World's Fair to be held in New York City in 1939. Drs. Nathan B. Van Etten and Arthur W. Booth of New York.

The following appointments, made by mail during the interim between meetings of the Board, were confirmed.

Drs. Franklin G. Ebaugh, J. Allen Jackson, Walter L. Treadway and H. Douglas Singer to represent the Association on the Cooperative Committee for a Survey of Public Mental Hospitals in the United States.

Drs. Roger I. Lee, Nathan B. Van Etten and William C. Woodward to represent the Association at the meeting of the American Bar Association held in Boston the week of August 24, and Drs. Holman Taylor and E. H. Cary, at the meeting of the American Pharmaceutical Association held in Dallas, August 24-29.

Dr. C. B. Wright to represent the Association at the dedication of the monument to Dr. Perry H. Millard at Stillwater, Minn., on June 7.

APPROPRIATIONS

Appropriations were authorized to cover the expense of the first meeting of new committees, as well as for the Committee to Study Contraceptive Practices and Related Problems, for special exhibits on fractures and anesthesia for the next annual session of the Association, and for the renewal of the dramatized radio programs

RESIGNATION OF DR GEORGE MILLER MACKEE FROM
COUNCIL ON PHYSICAL THERAPY

The resignation of Dr George Miller MacKee tendered because of the necessity for curtailing his activities was accepted with regret and with a statement of the Board's appreciation of the splendid service he has rendered to the Council

MISCELLANEOUS

Matters pertaining to advertising methods, legislation, government activities concerned with medicine and public health and numerous other subjects were considered on which no action could be taken at this time but which will come before the Board from time to time in the future

RADIO BROADCASTS

Health Dramas to be Resumed October 13

The American Medical Association and the National Broadcasting Company present the second series of dramatized health broadcasts under the title *Your Health*, beginning October 13. The first broadcast in the new series will be the thirty-second dramatized cooperative broadcast under the title *Your Health*. The theme for 1936-1937 will differ slightly from the topic in the first series which was 'medical emergencies and how they

The program will be on the Red network and Pacific network of the National Broadcasting Company. The stations listed above are those to which the program is available.

It should be noted that a station may take the program or not. If a station included in the list is not broadcasting the program *Your Health*, it is possible that the management may be induced to broadcast the program if it receives evidences of local interest. The committee on education or other appropriate committee of the local medical society might take this matter up with the station management and tender cooperation in giving the program local publicity.

The topics are announced monthly in advance in *H3genia*, the *Health Magazine*, and three weeks in advance in each weekly issue of *THE JOURNAL*. The topics and speakers for October are as follows:

October 13 What to Do for Blind Children W W Bauer MD
October 20 Arthritis Morris Fishbein MD
October 27 Help for the Deafened W W Bauer MD

The time of the broadcast is Tuesday afternoon at 5 o'clock eastern standard time (4 o'clock central time, 3 o'clock mountain time, 2 o'clock Pacific time)

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH)

CALIFORNIA

Plague Infection.—According to *Public Health Reports* plague infection has recently been proved, by animal inoculation in four ground squirrels received at the laboratory of the state department of public health from localities near Hackamore, in Modoc National Forest, Modoc County.

Society News.—The Hollywood Academy of Medicine was addressed, September 24, by Dr Fred L Soper, Rio de Janeiro, Brazil, on *Jungle Yellow Fever*. New Epidemiologic Entities in South America.—Dr Oswald S Lowsley, New York addressed the San Francisco chapter of the Pan American Medical Association, September 23, on "Modern Renal Surgery" and conducted a clinic at the San Francisco County Hospital.—At a special meeting of the staff of Peralta Hospital, Oakland, Dr Olin H Garrison presented a case report on pernicious anemia and Dr Edward F Roberts, New York gave an illustrated address entitled "Pernicious Anemia and Parenteral Liver Therapy."—The San Francisco County Medical Society will be addressed October 13 by Dr Howard C Naffziger, San Francisco, on "Progressive or Malignant Exophthalmos Related to Thyroid Disease."

CONNECTICUT

Sir Joseph Barcroft Gives Terry Lectures.—Sir Joseph Barcroft, professor of physiology, University of Cambridge, England, delivered the Terry Lectures at Yale University October 5-7, on "Three Aspects of the Relation of Environment to Organism." The titles of the individual lectures were "Mental Efficiency Considered in Relation to Some Properties of the Blood," "Origins of Behavior in the Fetal Environment" and "The Transition from Fetal to Neonatal Conditions."

DISTRICT OF COLUMBIA

Society News.—The Medical Society of the District of Columbia will be addressed October 21 by Drs William J Mallory, John A Reed and Maurice Protas on "Observations on the Use of Insulin Prothrombin in the Treatment of Diabetes Mellitus" and Dr Garnet W Alt. Recent Advances in Proctology. Edmund A Walsh PhD will address the society October 14.

Personal.—Dr Arthur C Christie was recently elected to honorary membership in the Societa Italiana di Radiologia Medica and in the Deutsche Röntgen Gesellschaft.—Dr William A Warfield Sr., for forty years surgeon-in-chief at Freedmen's Hospital, a government institution will be retired November 17, newspapers announce. Dr Warfield is professor of abdominal surgery at Howard University College of Medicine. Dr Thomas Edward Jones will succeed Dr Warfield at the hospital.

are met." The new series will be built around the central idea that 100,000 American physicians in great cities and tiny villages who are members of the American Medical Association and of county and state medical societies stand ready day and night to serve the American people in sickness and in health.

FLORIDA

New Dental Bureau—The state board of health has created a new bureau of dental health with E. C. Geiger DDS, Jacksonville, in charge. It is planned to carry out a program of dental health education that will include the examination of every school child in the state. Recommendations will be made to parents and in cases of underprivileged children a plan for free dentistry is being worked out. It is reported a recent survey of school children of the state revealed that from 75 to 90 per cent of those examined were suffering from dental defects.

IDAHO

Society News—Drs. William F. Passer, Twin Falls, and Joseph N. Davis, Kimberly, addressed the South Side Medical Society, Twin Falls, recently, on Infant Feeding and The Rocky Mountain Spotted Fever, respectively.

ILLINOIS

Prevalence of Poliomyelitis—A record of 206 cases of infantile paralysis in Illinois in September was the highest monthly total of cases of this disease since 1917 according to the *Chicago Tribune*, September 28. Because of the general increase in prevalence throughout the state the Illinois department of health has requested volunteer contributions of blood from persons who have recovered from the disease in the last fifteen years.

Society News—Dr. Franklin E. Walton, St. Louis, addressed the Vermilion County Medical Society in Danville, September 2, on "Diagnosis and Management of Biliary Tract Diseases."—Dr. Earl O. Latimer, Chicago, addressed the Will Grundy County Medical Society, September 30, on treatment of appendicitis.—At a meeting of the Du Page County Medical Society, September 16, Dr. Clarence J. McMullen, Chicago, spoke on diabetes mellitus.—Speakers before the La Salle County Medical Society in Ottawa, September 23, were Drs. Jacob J. Singer, St. Louis, on "Diagnostic Methods in Obscure Chest Conditions," and Willard F. Arbuckle, St. Louis, "Pulmonary Conditions Revealed by the Bronchoscope."—Dr. William H. Holmes, Chicago, discussed undulant fever before the Sangamon County Medical Society, October 1.—At a meeting of the DeWitt County Medical Society in Clinton, September 23, Dr. Robert S. Bergholt, Chicago, spoke on heart disease.

Chicago

Personal—Dr. Mary Stone, head of the Bethel mission center, Shanghai, China, was guest of honor at a dinner given by women physicians of Chicago at the Women and Children's Hospital.

The Bacon Lectures—Dr. Frank W. Lynch, professor and head of the department of obstetrics and gynecology, University of California School of Medicine, San Francisco, will deliver the seventh annual Charles Sumner Bacon Lectures at the University of Illinois College of Medicine, October 16 and October 23. Dr. Lynch's subjects will be "Carcinoma of the Uterus" and "Uterine Fibroids."

Society News—The Chicago Council of Medical Women was addressed October 2 by Dr. Estlier T. Frankel on "Indications for Physiotherapy."—Dr. George E. Bennett, Baltimore, addressed the Chicago Orthopaedic Society, October 9, on "Acute, Recurrent and Old Dislocations of the Shoulder."—Drs. Paul H. Harmon and Carroll O. Adams, Pyogenic Arthritis of the Hip, with Special Reference to Pathological Dislocation and Treatment.

Mills Foundation Aids Work on Cancer—Wesley Memorial Hospital announces the receipt of an annual allotment from the Davella Mills Foundation, Montclair, N. J., for the treatment of cancer patients and research on cancer. The sum of \$7,500 was allotted for 1936 and in June of each year an appropriation will be made. The Davella Mills Foundation was created in 1934 by Mr. David B. Mills and his wife Ella. The income is used to further the activities of several philanthropies.

INDIANA

Society News—Dr. Bert E. Ellis, Indianapolis, discussed "Obstruction of the Larynx" before the Fayette-Franklin Medical Society in Brookville, September 8.—Dr. Charles P. Emerson, Indianapolis, addressed the Gibson County Medical Society in Princeton, September 14, on "Later Developments in the Early Recognition, Treatment and Control of Cancer."—Dr. Baruch M. Edlavitch, Fort Wayne, presented a clinical study of insulin protamine before the Fort Wayne Medi-

cal Society, September 15.—At a meeting of the Madison County Medical Society in Anderson, September 21, Dr. Henry O. Mertz, Indianapolis, discussed "Relation of Urological Diseases to the Differential Diagnosis of General Abdominal Diseases."—Dr. Frank Forry, Indianapolis, addressed the Carroll County Medical Society in Burlington, September 10, on cancer.—The Hendricks County Medical Society was addressed in Danville, September 17, by Dr. Jewett V. Reed, Indianapolis, on "Injuries of the Skull and Traffic Accidents of the Day."—Dr. Roscoe L. Sensenich, South Bend, addressed the Tippecanoe County Medical Society at Lafayette recently on "Political Trends Today Affecting Medical Practice."

KENTUCKY

New Health Officers—Dr. James W. Miller, recently health officer of Gallatin County at Warsaw, has been transferred to Green County to succeed Dr. Jesse M. Dishman. Greensburg recently appointed in Caldwell County. Dr. Emil A. Steiner, Cleveland, Ohio, has been appointed in Pulaski County, and Dr. James O. Nall, recently of Murray in Trigg County.

LOUISIANA

Health at New Orleans—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million for the week ended September 26 indicate that the highest mortality rate (187) appears for New Orleans and for the group of cities as a whole, 10.2. The mortality rate for New Orleans for the corresponding period last year was 17.4 and for the group of cities 10. The annual rate for eighty-six cities for the thirty-nine weeks of 1936 was 12.2 as against a rate of 11.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

MASSACHUSETTS

Honorary Degrees Conferred at Harvard Tercentenary—At the exercises commemorating the tercentenary of Harvard University, September 18, honorary degrees of doctor of science were conferred on the following, among others, who took part in the conferences:

Dr. Edgar Douglas Adrian, Foulerton, professor of physiology of the Royal Society and fellow of the Trinity College, Cambridge.
Dr. Joseph Barcroft, professor of physiology, University of Cambridge.
Dr. James B. Collip, professor of biochemistry, McGill University, Faculty of Medicine, Montreal.
Dr. Ross Granville Harrison, Sterling, professor of biology, Yale University School of Medicine, New Haven, Conn.
Sir Frederick Gowland Hopkins, professor of biochemistry, University of Cambridge.
Dr. Bernardo A. Houssay, director, Institute of Physiology, Buenos Aires.
Dr. Pierre Marie Felix Janel, professor of psychology, College of France, Paris, France.
Dr. Carl Gustaf Jung, Kusnacht, near Zurich, Switzerland.
Dr. August Krogh, director of the Zoophysiological Laboratory at the University of Copenhagen.
Dr. Karl Landsteiner, Rockefeller Institute for Medical Research, New York.
Dr. Kiyoshi Shiga, president of the Governmental University, Keijo, Chosen, Korea.
Dr. Hans Spemann, professor of zoology, Faculty of Natural Sciences and Mathematics, University of Freiburg, Germany.

MICHIGAN

State Medical Election—Dr. Henry Cook Flint was chosen president elect of the Michigan State Medical Society at its annual meeting in Detroit, September 21-24, and Dr. Henry E. Perry, Newberry, was installed as president.

Society News—Dr. Geza de Takats, Chicago, addressed the Calhoun County Medical Society in Battle Creek, September 1, on "Treatment of Varicose Veins."—The Allegan County Medical Society was organized, August 18, with Drs. George H. Rigterink, Hamilton, as president, Olin H. Stuck, Otsego, vice president, Morley B. Beckett, Allegan, county health officer, secretary, and Roy A. MacNeill, Allegan, treasurer.—Dr. Louis B. Wilson, Rochester, Minn., gave a lecture in the graduate series sponsored by the Wayne County Medical Society, Detroit, October 5, his subject was "National Specialty Qualifying Boards in Relation to Graduate Medical Education."—The opening meeting of the new season of the West Side Medical Society, Detroit, October 1, was addressed by Drs. Warren O. Nelson and Charles G. Johnston, both of Detroit, on "Some Endocrine Influences in Atypical Growth and Some Problems Relating to the Care of the Patient with Gallbladder Disease," respectively.

NEW MEXICO

Personal—Dr James R. Scott, Albuquerque, has resigned as health officer of the third district, Dr Julian O. Long has been provisionally appointed to succeed him.

Hospital News—A ten bed private hospital was recently opened at Tularosa, with Dr Clyde H. Hemphill as chief of staff, Dr Leo R. Gaddis, Alamogordo, chief surgeon, and Dr John D. Robinson, in charge of general medicine. It is known as the Hemphill Hospital.

County Health Demonstration—San Miguel County has been selected for a demonstration of public health service as part of a statewide plan for maternal and child health services, with funds derived in part from the county and in part from money allotted to the state by the U. S. Children's Bureau under the Social Security Act. The program as outlined in the *New Mexico Health Officer* includes general public health nursing with particular attention to health education, to cooperate with New Mexico Normal University in a plan that includes extension of health education in the county and establishment of antepartum, maternal, infant welfare, preschool and school children's clinics for promotion of public health. These clinics will be held if possible in cooperation with the local medical society, according to the bulletin.

NEW YORK

Society News—The New York State Association of Public Health Laboratories will hold its midyear meeting November 6 at the state laboratory in Albany.—Dr Robert P. Dobbie, Buffalo, addressed the Medical Society of the County of Niagara September 8 on surgery of the biliary tract.—Motion pictures by Drs Allen B. Kanavel, Chicago, on 'Diagnosis and Treatment of Infections of the Hand' and Grover C. Penberthy, Detroit on 'Treatment of Burns' were shown at a meeting of the Dutchess County Medical Society, Poughkeepsie, September 9.

New Buildings for Crippled Children's Hospital—Several new buildings at the New York State Reconstruction Hospital at West Haverstraw were dedicated September 24. The buildings which have been built since the transfer of the institution to the state department of health in 1931 consist of two wards, a school for all grades through high school, a dining room and kitchen, a power plant and a treatment center. The treatment center includes facilities for electric massage, electrotherapy and hydrotherapy, a large recreational and correctional swimming pool and two smaller treatment pools. Governor Lehman gave the dedicatory address and other speakers were Drs Edward S. Godfrey Jr., state health commissioner, and Walter Thompson, president of the hospital's board of visitors.

New York City

Serum Laboratory Established—The Manhattan Convalescent Serum Laboratory has been established in the research laboratory of the department of health for preparation and distribution of immune serums for measles, scarlet fever and other communicable diseases. Dr William Thalheimer is in charge of the new service.

Personal—Mr Lawrence K. Frank, formerly associate director of education of the General Education Board has been appointed assistant to the president of the Josiah Macy Jr. Foundation. Dr Ludwig W. Kast is the president.—Drs Edgar Mayer and James Burns Amberson Jr. have been appointed by the state industrial commissioner as consultants on dust diseases.

Society News—A symposium on obstetrics was presented at the meeting of the Medical Society of the County of Queens September 29, by Drs Edward S. Godfrey Jr., Albany, state health commissioner, Harriet M. White, Richmond Hill, Moses Cohen, Long Island City, Henry C. Eichacker, Brooklyn, Walter H. Kerby, Woodhaven, George J. Lawrence, Flushing, and James P. McManus, Hollis.—The second series of lectures to the public sponsored by the New York Academy of Medicine was begun October 8 by Dr Smith Ely Jelliffe who spoke on 'The Historical Background of Psychiatry'.

NORTH CAROLINA

Society News—Drs William G. Bands and John W. Same, Lincolnton, addressed the Catawba Valley Medical Society, Hickory, September 8 on 'Diagnosis and Treatment of the Common Causes of Indigestion and Purpura Haemorrhagica' respectively.—Dr John H. Musser, New Orleans, addressed the Puncombe County Medical Society, Asheville, August 24 on coronary occlusion.

Personal—Dr Martin L. Stevens, Asheville, has been appointed a member of the board of trustees of the state tuberculosis sanatoriums.—Dr Paul P. McCain, superintendent of the State Sanatorium, Sanatorium, received the honorary degree of doctor of laws at the annual commencement of the University of North Carolina.—Dr Ruth M. Collings, assistant physician to Woman's College of the University of North Carolina, Greensboro, has been appointed college physician to succeed Dr Anna M. Gove, who has retired.—Dr Maria S. Naples, Cleveland, Ohio, has been appointed assistant.—Dr Alfred D. Gregg, Liberty, has been appointed health officer of Vance County, succeeding Dr Zack P. Mitchell, Henderson, who has been appointed health officer of Swain and Graham counties.

OHIO

Personal—Dr Paul C. Bratten, New Bremen, has been appointed health officer of Shelby County to succeed the late Dr Alfred B. Lippert.—Dr Gordon E. Savage, Osborn, has been appointed health officer of Greene County, heretofore the position has been half time.

Fiftieth Anniversary of Practice—The Tuscarawas County Medical Society entertained Dr Byron G. Anderson, Uhrichsville, at a dinner September 10 in honor of his fiftieth anniversary of medical practice. Speakers who paid tribute to the 78 year old physician included Drs Jonathan Forman, Columbus, Elliott D. Moore and John M. Smith, New Philadelphia, Daniel W. Shumaker, Dover, and Mr Charles S. Nelson, Columbus, secretary, Ohio State Medical Association.

Society News—Dr John A. Toomey, Cleveland, addressed the Columbus Academy of Medicine September 28, on 'Differential Diagnosis of Epidemic Meningitis and Other Meningeal Irritations'.—Dr Paul W. Palmer, Lorado, W. Va., addressed the Fayette County Medical Society, Washington Courthouse, September 3, on hemorrhoids.—Speakers at a meeting of the Miami County Medical Society in Troy, September 4, were Drs Lauren N. Lindenberger, Troy, on 'Indications for Cesarean Section' and George R. Upton, Piqua, 'Surgical Technique for Cesarean Section'.—Dr Raymond C. McKay, Cleveland, addressed the Mahoning County Medical Society, September 15, on 'Collapse Treatment of Pulmonary Tuberculosis'.—Dr Max M. Zininger, Cincinnati, addressed the Auglaize County Medical Society in St. Marys, September 17, on 'Diagnosis and Treatment of Acute Abdominal Emergencies'.—Dr Morris Fishbein, Chicago, editor of THE JOURNAL, addressed the Academy of Medicine of Cincinnati October 6, on 'New Plans for Medical Service'.

OKLAHOMA

Society News—Dr Henry H. Turner, Oklahoma City, addressed the September meeting of the Garfield County Medical Society at Enid on the endocrine glands.—At a meeting of the Southern Oklahoma Medical Association in Norman September 1 speakers were Drs Wendell Long, on 'Treatment of Menorrhagia', Raymond Murdock, 'Diagnosis and Treatment of Rectal Diseases', and Kelley West, 'Colles Fractures and Associated Fractures of the Wrist'. All the speakers are from Oklahoma City.

PENNSYLVANIA

Personal—At a meeting of the state board of medical education and licensure, August 27, James A. Newpher was elected secretary of the board to succeed Clarence L. Achley.

Society News—Dr Grover C. Penberthy, Detroit, addressed the Erie County Medical Society, September 8, on 'Ten Years Study of Empyema in Children'.—Dr Walter F. Donaldson, Pittsburgh secretary, Medical Society of the State of Pennsylvania, addressed the Dauphin County Medical Society, Harrisburg, September 2 on 'Social and Economic Problems Facing the Medical Profession Today'.—Dr Bernard J. Alpers, Philadelphia, addressed the Harrisburg Academy of Medicine September 15 on 'Nervous Complications Encountered in General Practice'.—Dr Charles A. Behney, Philadelphia, addressed the Cumberland County Medical Society in Carlisle in September on 'Excision of the Sympathetic Nerves for the Relief of Pelvic Pain'.

Philadelphia

Personal—Dr and Mrs David W. Levy celebrated their fiftieth wedding anniversary September 21.—Dr Edward Martin, Media, has been elected president of the Philadelphia board of education.

Society News—A symposium on prevention of tuberculosis will be presented before the Philadelphia County Medical Society October 14 by Drs Esmond R. Long, William G. Terrell and Frank A. Craig, Philadelphia and Edith E. MacFarlane.

Dexter, Harrisburg, state secretary of health — Speakers before the Obstetrical Society of Philadelphia October 1 were Drs Fred B Nugent, Reading Pa on 'The Primiparous Genitalia After Forceps Delivery', Walter Sussman, 'A New Method for the Control of the Early Nausea and Vomiting of Pregnancy' and I Charles Lintgen 'The Incidence of Uteral Stricture in Lower Abdominal Pain in Women' — Drs Arthur Finkelstein, Wilmington Del and George W Chamberlin addressed the Philadelphia Roentgen Ray Society, October 8, on 'Roentgen Studies of the Ischiopubic Junction' and 'Treatment of Hypophyseal Stalk Tumors by Evacuation and Irradiation' — At a meeting of the Philadelphia Academy of Surgery, October 5, speakers were Drs Isidor S Ravdin and Jonathan E Rhoads on 'Terminal Ileitis', Lynn M Rankin, 'Acute Fractures of the Pelvis' and George M Dorrance, 'Treatment of Webbed Fingers Proper Age of Operation.' Dr Francis C Grant presented a memoir to the late Dr Charles H Frazier

Pittsburgh

Hospital News — The annual Mercy Day reunion was held at Mercy Hospital, September 24 with Dr Frank H Lahav, Boston as guest speaker on disease of the gallbladder

Society News — Drs Harry M Margolis and Philip A Fax addressed the Allegheny County Medical Society, September 15 on 'Clinical Use of Insulin Protamine' and 'Review of the Anesthetic Agents and Methods Used in 1936' respectively, and Dr Simon H Ratner reported a case of pulmonary mycosis

TEXAS

State Provides Quarters for Visiting Physicians — Through a provision of the appropriation bill passed by the last legislature graduate instruction for practicing physicians is to be made available at the State Tuberculosis Sanatorium, Sanatorium, and the sanatorium has built a cottage as a residence for the visiting physicians. The cottage was to be ready for occupancy October 1, with quarters for eight physicians. Special courses will be given in artificial pneumothorax, phrenic nerve operations and x-ray studies. The cost of the new building was about \$13,000

Society News — Drs Herbert M Westphal Weslaco and Loyal H Moore, McAllen addressed the Hidalgo-Starr Counties Medical Society, July 16, on 'Undulant Fever' and 'Treatment of Common Diseases of the Middle and External Ear' respectively — Dr James M Hooks Paris addressed the Lamar County Medical Society, Paris, July 2 on chronic ulcers — Drs William A. Smith and Seaborn J Lewis Beaumont discussed 'Epithelioma' and Laboratory Technic in Diagnosis respectively before a meeting of the Liberty Chambers Counties Medical Society, Anahuac, July 11 — Speakers before the Palo Pinto County Medical Society, Mineral Wells, July 6 were Drs Joe H McCracken and Waldo B Lasater Mineral Wells on diseases of the thyroid gland — The Texas Public Health Association will hold its annual meeting in Kilgore, October 14-16. Among speakers will be Drs Reginald M Atwater, New York, executive secretary, American Public Health Association, John Rosslyn Earp, state health officer, New Mexico, Santa Fe, Howard R Dudgeon, Waco, president, State Medical Association of Texas, and Martha M Eliot, Washington, D C, assistant chief, U S Children's Bureau — Dr Charles E Collins Waco addressed the Hill County Medical Society, Hillsboro in September on 'The Heart in Surgical Mortality' — At the meeting of the Dallas County Medical Society, Dallas, October 22 speakers will be Drs Thomas H Cheavens and Charles F Carter on 'Mental Disturbance Due to Bromide Intoxication' and Addison Gerald Moore, Camden, Ind, on 'Hypertension and Cardiac Complications'

VERMONT

State Medical Meeting at Burlington, October 15-16 — The one hundred and twenty-third annual meeting of the Vermont State Medical Society will be held in Burlington, October 15-16. A preliminary program lists the following speakers among others

Dr John H J Upham, Columbus, Ohio, President Elect, American Medical Association, Heart Disease in Middle and Past Middle Life
Dr Adolphus D Rood, Springfield, Mass, Postoperative Pulmonary Atelectasis
Dr Royd R Sayers, Washington, D C, Respiratory Dust Diseases
Dr Doris A Murray, Washington, D C, Maternal and Child Health
Dr Franklin P Lowry, Newton, Mass, The Value of Physical Therapy in the Practice of Medicine
Dr Guy L Hunter, Baltimore, The Urinary Tract in Relation to Diagnosis of Abdominal and Pelvic Lesions

There will also be a symposium on vascular diseases with the following speakers all of Boston: Drs Robert S Palmer

Theodore C Pratt, Robert R Linton, Henry H Faxon and Reginald H Smithwick. Dr Lester W Burbank, Cabot, is president of the society

WEST VIRGINIA

Personal — Dr Jesse A Jamison has resigned as health officer of Fairmont after fifteen years' service. — Dr Rexford A Burdette, Charleston has been named director of the Monongalia County health department, succeeding Dr Robert C Farrier who recently resigned to accept a similar position in Delta County, Mich

University News — A college of pharmacy has been established at the University of West Virginia, replacing the former department of pharmacy in the school of medicine. Dr Andes graduated from the Louisiana State University Medical Center in June. In 1932 he received his degree of doctor of philosophy from Western Reserve University. He is 32 years of age.

GENERAL

Outbreaks of Typhoid — Seventeen cases of typhoid fever among workers on a highway project near Carlisle, Pa, were reported by newspapers, September 15. There was one death. It was found that the workmen drank from a pipe line from a stream which was contaminated. — Two deaths have occurred in an outbreak of forty-two cases at the Columbus State Hospital, Columbus, Ohio, it was reported, September 10. — Forty-nine cases with three deaths had occurred in the outbreak in Englewood, N J, and surrounding towns up to September 22. This epidemic was attributed to a spring in Englewood.

Special Broadcast on Y M C A Anniversary — The New York City division of the Young Men's Christian Association announces a special broadcast, October 11, to observe the one hundred and fifteenth anniversary of the birth of Sir George Williams, founder of the organization. Speakers in the broadcast, which will be from 4:30 to 5 p m, eastern standard time, will include, among others, J Edgar Hoover, director of the Federal Bureau of Investigation, Dr Morris Fishbein, Chicago, editor of THE JOURNAL, Miss Mildred H McAfee, president of Wellesley College, Wellesley, Mass, and Eddie Cantor, Hollywood. The Y M C A was founded by Sir George in England ninety-two years ago.

Bequests and Donations — The following bequests and donations have recently been announced:

Pennsylvania Hospital, Episcopal Hospital, Home of the Merciful Savior for Crippled Children and the Home for Incurables, Philadelphia are among institutions that will eventually receive one sixteenth of the estate of Frederick McOwen, estimated at more than \$4,000,000.

Montefiore Hospital, New York, \$1,000 from the estate of the late Ida H Saks

St Joseph's Hospital for Consumptives, Bronx, \$1,000 by the will of the late Ann Dillon

Pennsylvania Hospital, Philadelphia, \$21,000 by the will of Miss Emily Fell Dawson

St Luke's Hospital, Chicago, \$20,000 by the will of the late Mrs Grace Witbeck Barrell

Memorial Hospital for the Treatment of Cancer and Allied Diseases, New York, \$50,000 to equip a cancer treatment room by the will of Mrs Mary L C Earle

Jefferson Medical College, Philadelphia, \$5,000 from the estate of the late Dr Thomas Macrae

Lebanon and Montefiore hospitals for chronic diseases, New York, \$1,000 each by the will of Rudolph H Abraham

St Joseph's Hospital, Yonkers, N Y, \$1,000 by the will of Edward J Doran

Presbyterian and New York hospitals, New York, each \$2,201.491 by the will of the late Mary Gardiner Thompson

St Luke's Hospital, New York, \$42,500. National Society for Prevention of Blindness, \$5,000 and the New York State Reconstruction Home, West Haverstraw, \$5,000 by the will of the late George Blagden. St Luke's will also receive half the residuary estate after the death of named beneficiaries. The estate was valued at nearly \$5,000,000.

Public Health Meeting — The sixty-fifth annual meeting of the American Public Health Association will be held in New Orleans, October 20-23. The preliminary program includes the following speakers:

Dr John Sundwall, Ann Arbor, Mich, Training of Vital Statisticians
Fred W Tanner, Ph D, Urbana, Ill, Problems in Food Preservation
Dr Thomas Francis Jr, New York, Epidemiologic Studies in Influenza
Dr Martha M Eliot, Washington, D C, Infant and Maternal Welfare from the Aspect of Social Security
Dr Royd R Sayers, Washington, D C, Industrial Hygiene Activities in the United States
Dr William Lloyd Aycock, Boston, The Nature of Autacesthesiologic Susceptibility to Polymyositis

Special sessions will be devoted to mental hygiene, advances in public health and mosquito-borne diseases. There will be symposiums on milk and dairy products, enteric fevers, syph-

ills, food poisoning, sanitation of eating utensils, and intestinal parasites, including protozoa. One session on public health education will be addressed by Mr Howard Blakeslee, science editor of the Associated Press, New York, on 'The Newspaper—Science in the Press—The Daily, the Weekly, and the Interests of the Readers of Each,' and Miss Judith Waller, educational director, central division, National Broadcasting Company, Chicago, "The Radio." The first general session will be held Tuesday evening, when Dr Thomas Parran surgeon general, U S Public Health Service, Washington, D C will deliver his address as president-elect of the association. On this occasion the winner of the Sedgwick Memorial Medal will be announced. The American Association of School Physicians, the Association of Women in Public Health and Delta Omega will also meet during this time.

FOREIGN

Survey of Rural Hygiene—A commission from the League of Nations is making a survey of rural hygiene in countries of the Far East preparatory to a conference to be held in Java in August 1937. Mr A S Haynes formerly colonial secretary in Malaya, is head of the commission, which visited the Philippine Islands in June and was to go later to the Dutch East Indies, Singapore and South India.

Traffic Signs Direct Travelers to Physicians—Directions for reaching the nearest physician are being added to traffic signs near dangerous curves and intersections in Czechoslovakia, according to a report to the U S Department of Commerce from the commercial attache in Prague. It is believed that the psychologic effect is excellent and that the information is of value in case of accidents. An inscription giving the location and distance to the nearest physician is placed below a red field in a blue frame.

Typhoid Outbreak at British Resort—Three hundred and eighty-five cases of typhoid were reported between August 21 and September 4 in Bournemouth, England, and two adjacent towns, Poole and Christchurch. It was found that the infection came from unpasteurized milk and treatment of the offending supply was begun at once. At Bournemouth it was necessary to take over a large house to provide extra hospital accommodations for the patients. Bournemouth had 222 with seven deaths, Poole 143 with two deaths and Christchurch 20.

Government Services

Changes in Public Health Service

Drs Ernest E Huber and Clifford R. Eskey have been promoted and commissioned as surgeon and senior surgeon respectively in the regular corps of the U S Public Health Service. Other changes in the service include the following transfers:

Passed Asst. Surg. Frederick Paul Buron relieved at Hamburg Germany on arrival of Sr. Surg. Herbert A. Spencer and assigned to Naples, Italy, for duty in the office of the consul general.

Passed Asst. Surg. Mason V. Hargett relieved at Stuttgart and ordered to London, England, for duty in office of American consulate.

Surg. Walter G. Nelson relieved at Naples, Italy, and assigned to Berlin, Germany.

Medical Director Claude H. Lavinder relieved as chief medical officer of U S Marine Hospital Ellis Island, N Y, and directed to assume charge as director of public health district number 1 comprising the states of Maine, New Hampshire, Vermont, Massachusetts, Rhode Island, Connecticut, New York and New Jersey.

Maryland and the Social Security Program

The plan of Maryland to provide care for its crippled children under the social security program was approved August 1. This makes thirty-seven states and the District of Columbia and Alaska with these plans. Eleven states and Hawaii have not yet been able to make adequate arrangements for participation, although in some cases the necessary preliminaries can be completed soon and grants under the 1937 appropriation made. During the first five months of the year \$732,492.33 was paid to the thirty-six participating states. Alaska and the District of Columbia. The sum available for apportionment during the fiscal year ending June 30, 1937, is \$2,450,000 based on a specific allocation for all the states, Alaska, Hawaii and the District. A total of \$400,000 remains to be apportioned on the basis of the number of crippled children in need of care, relative costs of care and state funds available. This allotment cannot be made until all state plans for the period covered have been received.

Sept 1 1935.

Report on the Treatment of Dementia Paralytica

The Mental Hospitals Committee of the London County Council has made an important report on the treatment of dementia paralytica. Because of its vast hospital system, the council has on this subject experience at its disposal on a scale impossible elsewhere. For some time Dr F. L. Golla, director of the central pathologic laboratory at the Maudsley Hospital, has been engaged in coordinating the treatment of dementia paralytica at all the council's hospitals, keeping records and following up the after histories of patients who were discharged after treatment. It is pointed out in the report that before the advent of modern therapy there was no real recovery from the disease. A few patients might linger on for a number of years, in exceptional cases for a long period, but the discharge rate was insignificant and the majority of patients died within a short time of admission. In the six years 1908-1913 there were 2,545 cases of dementia paralytica in the council's mental hospitals. Of these, 2034 (almost 80 per cent) proved fatal. The modern treatment was not then in use. Comparison is made with the six years 1930-1935, when 1,914 cases were in the hospitals and the modern treatment was used in every case in which this was possible. The untreated patients comprised those admitted moribund or suffering from grave physical disabilities which rendered active treatment impossible. Eighty-five per cent of the patients received some special form of treatment, 78 per cent pyrexial therapy with or without drug treatment, and 7 per cent drug treatment only. On Dec 31, 1935, 782 of the patients (40.8 per cent) had died, seventy-eight were taken out of the council's care, 379 (19.18 per cent) were discharged and 430 remained in the hospital. Comparison of the two series of cases shows that: 1. Even in the total of treated and untreated cases the mortality rate had been halved. 2. One fifth of the cases in the second series had been discharged, the cure in the majority being permanent. Many of the persons discharged are now filling positions of responsibility. 3. There is an increase of 208 in the resident dementia paralytica cases which is made up of cases in which the lethal progress has been arrested but the mental symptoms have not permitted discharge from care. The pyrexial treatment was carried out with malaria and drugs, the specific drug treatment, and by various preparations of arsenic and bismuth.

The Fitting of Artificial Limbs

The work of the ministry of pensions in providing artificial limbs for the victims of the great war has resulted in the creation of a highly specialized and efficient organization at Queen Mary's Hospital, Roehampton and affiliated centers throughout the British Isles. The unprecedented demand for limbs has been a stimulus to the production of improved technical devices and higher standards of material and workmanship which have been guided by the surgeons responsible for selecting the most suitable type and supervising the fitting. The specialized knowledge and experience acquired has been freely communicated to the medical profession. Lectures and demonstrations on amputation stumps and on the fitting of artificial limbs have been given to medical representatives at various public services and medical schools. During 1935 fewer than 132 surgeons attended these lectures. There has been a widely expressed wish that the benefit of the military service should be extended to civilians, which has already been

done in the case of civilians living near or in London. With a view to the extension of the benefits, the minister of pensions was requested to allow the services of the limb fitting surgeons in the provinces to be made available. They were consulted in the matter and their replies show that they recognize the deficiencies of the existing practice, in which the patients are largely dependent on the makers of artificial limbs whose knowledge of anatomy may or may not be adequate. The minister has therefore granted the request. Under an agreement to be entered into, fees will be charged which will cover all expenses incurred by the ministry of pensions. The new arrangement will not be allowed to interfere with the practice of any independent surgeon who may wish to supervise the adjustment of an artificial limb in a case in which he has been concerned or with the supply of artificial limbs by any firm of limb makers that it may be desired to employ.

The Influence of Diet on Caries

The Committee for the Investigation of Dental Disease appointed by the Medical Research Council has issued a final report. The earlier reports gave the results of Mrs. May Mellanby's well known experiments on animals and children which have been reviewed in previous letters. She produced a large mass of evidence to show that nutrition and not oral hygiene, as was supposed, was the main factor in the decay of teeth. She showed that the liability of a tooth to decay depended largely on the perfection of its structure, which in turn depended on nutritional influences during growth both antenatal and postnatal. She found that ill formed (hypoplastic) teeth were much more common than had been supposed. For their formation the teeth require adequate supplies of calcium and phosphorus, and an ample supply of vitamin D to ensure that these are put to use. The same factors control the health of the teeth during the rest of their lives and the healing of caries.

The general object of the investigation on which this final report is based was to test the theory that nutrition is the dominant factor in determining the structure of teeth and their resistance to decay, particularly the supply of specific food elements in early life. It was impossible to investigate all nutritional influences, so the test was confined to observing the effects of adding one factor to the diet of children—vitamin D, in the form of either cod liver oil or irradiated ergosterol. The investigations were made in three similar institutions in the neighborhood of Birmingham, maintained on the cottage home system under the poor law authority. The children were recruited from the poor of Birmingham and were from 5 to 14 years of age. They were well cared for and well fed according to the recognized standards. The effect on the initiation and spread of caries of adding vitamin D and other substances to the basal diet was observed. For this purpose the children were divided into three groups, to which an addition in the diet was respectively made of treacle, olive oil or cod liver oil. The quantity varied according to age. Thus for children from 5 to 8 years of age the quantity of treacle varied from 28 to 42 Gm., of olive oil from 14 to 21 cc., and of cod liver oil from 14 to 21 cc. The incidence of carious cavities in freshly erupted teeth was 12 per cent in the cod liver oil group which was only half that in the treacle group and two thirds that in the olive oil group. In the deciduous teeth the protective action of the cod liver oil was not so well marked. It is claimed that this elaborate investigation shows conclusively that a relatively high vitamin D content of the food can do much to diminish the incidence of caries if given during the development of the teeth, that a beneficial effect may be obtained if the vitamin is given at a fairly late stage of development and that even when it is given after the eruption of the teeth the onset and spread of caries is delayed.

Instruction in Protection Against Air Raids and Poison Gas Attacks

National schemes for the protection of the civil population in cases of air attack are being actively prepared by the air raids precautions department of the government in cooperation with local authorities. It is realized that the range, speed and capacity of modern aircraft enable sudden attacks to be made on a heavy scale, which would cause great damage if there should be no previous organization to deal with the situation. Although a convention exists prohibiting the use of gas in war, the possibility of its being violated, as in the case of Abyssinia, cannot be ignored. It is with regard to this that the interest of the medical profession is particularly desired. The air raids precautions department has discussed the whole position with the General Medical Council, the British Medical Association and the deans of the medical schools. A scheme has been devised to cover the instruction of graduates, undergraduates and nurses. Specially selected and trained physicians will conduct special courses under the auspices of the deans of the medical schools, the British Medical Association and the General Nursing Council. The courses will be both theoretical and practical, including experience in wearing a modern type of respirator in actual gas. Courses will consist of some six or eight attendances. The instructors will travel about the country with special equipment to give the necessary instruction at convenient centers. The courses will be open to any registered physician, dentist or nurse.

Replying to an attack by the opposition stating that precautions against air attacks were inadequate Mr. Lloyd, under secretary to the home office, said in the house of commons that the two main classes of poison gas were the persistent and the nonpersistent. The nonpersistent would disperse naturally in a short time. The persistent were vaporized liquid and would contaminate an area and have lethal effects for several days unless steps were taken to prevent this. Prominent among the precautions were a warning system and control of public lighting. A trained service capable of finding out when gas was about and what gas it was was necessary. The decontamination of material from persistent gases should be performed. The government had sought the cooperation of the local authorities with regard to the provision of these services and the response had been satisfactory. Instruction was being given to persons who might have to undertake special duties in an emergency. Since the opening of the antigas school in April, 150 instructors had been given first-class certificates. The demand for instruction was so great that accommodations had to be doubled and another school of similar capacity erected in the northern part of England. Already all the instructors for the metropolitan police had been trained and instruction of the force was in full swing. In connection with this training the government had ordered forty mobile antigas chambers. The new respirator was 100 per cent efficient against all the gases known to the government and likely to be used in warfare. No other country was making such comprehensive provision for the protection of the civil population.

Professors Support Peace Campaign

Professors of psychology, anatomy and genetics are among the men of science who have signed the following statement on "Science and War," issued by the International Peace Campaign, London. "No scientist who reflects upon the uses to which his work is put can fail to recognize that the world is now faced with an unescapable choice—whether science shall be used for the benefit or the destruction of humanity. The International Peace Campaign has the support of thousands of articulate scientific workers in many countries who would like to be helping to build up a world of peace and friendship among the peoples but who day by day, see instead the restric-

tion and evil application of their labors" The signatories include Prof W E Le Gros Clark (anatomy, Oxford), Prof J B S Haldane (genetics, London), Assistant Professor J C Flugel (psychology, London), Julian Huxley (secretary, Zoological Society of London), Prof V G Childe (prehistoric archeology, Edinburgh), Prof H Levy (mathematics, London) and Prof T H Pear (psychology, Manchester)

Maternity Insurance

Supervision of insured women workers during pregnancy and parturition and that of nurslings has always been delegated to private organizations by the social insurance authorities, who distributed the necessary funds. Up to the present the diagnosis of pregnancy has had to be made after the fourth month and an antepartum examination carried out once a month thereafter. To encourage the women to go to the antepartum clinic regularly, an additional sum was granted to the assured. Every month following delivery, the mother was obliged to bring her infant to a nursing clinic, where an allowance was granted for cow's milk if it was needed to supplement the maternal feedings or if the latter was impossible. All of these were optional on the part of the assured during the antepartum and postpartum period, the underlying idea being that in view of the extra amounts paid by the caisses or insurance offices, the women would visit the clinics regularly during the antepartum period and bring their babies more frequently to the nursing clinics. Evidently this voluntary method was unsatisfactory, so that since Oct. 28, 1935, no allowances have been given during or after pregnancy unless the visits to antepartum and postpartum clinics are controlled by the caisses. In other words, supervision is obligatory if the women wish to receive insurance premiums during and after pregnancy.

A total of about \$20 is allowed for antepartum care. The first consultation must not be made later than the fifth month and includes a radioscapy, a Wassermann test, a urinalysis and as complete a general medical examination as possible. For a normal delivery the sum of 300 francs is granted, this amount being increased in cases of dystocia according to the nature of the complication.

Dr Dordives, in the August 15 *Siccle medical* believes that these new regulations will be a hardship for physicians in many rural districts, because the assured will be allowed to go to certain antepartum clinics only in larger centers and thus a large number of office consultations will be lost. In addition comparatively few physicians in smaller cities have the diagnostic resources at their disposal which the new law requires. Thus a new conflict will arise between the social insurance authorities and the medical profession unless the antepartum and postpartum centers to be established by the caisses or insurance bureaus will be satisfied to limit their task to diagnosis and then to refer the patients to their local physicians. The antepartum centers ought not to attempt either to treat those who are now obliged to consult them during the antepartum and postpartum periods or to refer them to some free or pseudo free institutions. The same question arises in connection with the general diagnostic centers which the social insurance authorities have proposed to open in all parts of the country.

Operative Results in Hyperthyroidism with Cardiac Complications

Team work on the part of two cardiologists, Lian and Gaquiere and a surgeon Welti in the management of severe cardiac complications of hyperthyroidism is well illustrated in a paper read at the June 3 meeting of the Academie de chirurgie of Paris. The forty-five cases were chosen from a

total of 450 cases of hyperthyroidism in which Welti recently operated, so one can say that cases presenting severe cardiac complications constitute about 10 per cent of the total number. The forty-five cases can be divided clinically into (a) seven complete arrhythmias (auricular fibrillation) without cardiac insufficiency, (b) thirty-six cases of cardiac insufficiency (eleven hypostoles, three left ventricular insufficiencies and twenty-four severe asystoles), twenty-four of the thirty-six patients in this group having a complete arrhythmia (auricular fibrillation), (c) one case of angina pectoris and (d) one case of paroxysmal tachycardia.

The authors are of the same opinion as the majority of French and American surgeons, that severe cardiac complications are more frequently encountered in cases of toxic adenoma than in exophthalmic goiter proper. They are also more frequent in men than in women: there were nine males to one female in the forty-five cases of cardiothyrosis. To obtain a satisfactory result in the latter, the operative removal should be an extensive one, hence subtotal thyroidectomy was performed in all except one patient, who refused further operation after a preliminary ligation, and three others on whom a complete thyroidectomy was carried out. None of the forty-five patients died in spite of the severe character of the cardiac condition.

A study of their cases has convinced the authors that cardiac complications are dependent, first, on the duration and intensity of the hyperthyroidism and, secondly, on the existence of cardiac lesions either as an associated condition or independent of the hyperthyroidism. Associated cardiac lesions are uncommon, but they persist even though the symptoms of hyperthyroidism have disappeared following thyroidectomy. The more important associated lesions are arteriosclerosis, hypertension and valvular lesions. Of these, the first two appear to be of chief importance, hence one encounters cardiac complications more frequently in elderly patients, the average age being 50 years in the cases in which such associated lesions existed. In cases of toxic adenoma the intensity of the hyperthyroidism, at the period when cardiac complications appear is in certain cases relatively unimportant. On the other hand, in the true case of exophthalmic goiter the intensity of the hyperthyroidism is the most important factor in the genesis of the cardiac complications that appear in younger patients.

In complete arrhythmia with auricular fibrillation, and this is the most constant finding in cardiothyroses operative intervention is followed by cure in half of the cases. Two factors influence these results: the duration of the arrhythmia and the coexistence or absence of cardiac insufficiency as well as its intensity. Return of sinus rhythm is sometimes delayed following operation. Quinidine sulfate has proved to be of great aid in regularizing the rhythm. In cardiac insufficiency of hyperthyroid origin the subtotal operation is followed by very gratifying results.

A study of end results in thirty-three cases revealed only four failures. In three of these improvement of the cardiac insufficiency was transitory, then the asystole recurred and the fourth patient died of pulmonary embolism three months after operation, at a period when marked improvement had already appeared.

The results in cases of hypostole are very much better than in patients with asystole. In the latter group of nineteen cases the result is perfect in seven, the asystole having completely disappeared and the orthoradiogram having returned to normal dimensions. In nine other patients the functional result is satisfactory but auricular fibrillation persists and the orthoradiogram remains unchanged. In a third subgroup of asystoles death occurred in three cases eighteen months, three years and five years after operation, without any amelioration of the cardiac condition.

To explain the failure of surgical treatment one must take into consideration not only the severity of the cardiac com-

cation but also the existence of associated cardiovascular lesions. The latter, however, are not a contraindication to operation. On the contrary, they are an indication, as shown by the authors.

A secondary total thyroidectomy is of no avail in improving the end results, and there is the additional risk of injury to the recurrent laryngeal nerve and may be followed by thyroid insufficiency. The earlier a subtotal thyroidectomy is performed, the more favorable will be the end results in cases of severe cardiac complications of hyperthyroidism.

A Series of Cases of Botulism

Five cases of botulism have been reported three at the May 29 and two at the June 12 meeting of the Société médicale des hôpitaux de Paris. The two cases were reported May 29 by Gilbert-Dreyfus, Ravina and his associates as following the ingestion of canned spinach and involved a man aged 41 and his daughter aged 11 years. The former had diabetes, which condition was not aggravated by the botulism but made a diagnosis difficult at the onset because of the resemblance of the clinical picture to an acidosis due to the diabetes. Guinea-pig inoculation of some of the contents of the can of spinach revealed the presence of *Bacillus botulinus*. The symptoms of intoxication were especially severe in the daughter. Remarkable improvement followed the use of the botulinus anatoxin and antibotulinus serum. The three additional cases, reported by Etienne May and his associates, followed the ingestion of smoked ham by all three of the patients. The first patient was given both the anatoxin and the serum, but the authors were unable to say whether or not recovery was due to this treatment. In the second case the use of strychnine and pilocarpine alone was successful, but the recession of symptoms was much slower than in the case in which the botulinus anatoxin and antibotulinus serum had been given.

Group Roentgenologic Examinations for Tuberculosis

The results of the examination of a large group of young men were reported in *THE JOURNAL*, Feb 22, 1936, page 639. The *Oeffentliche Dienst* has just published the results of several other such examinations and these data are submitted as supplementary to the earlier material. The examinations in question took place at two of the work camps in central Germany. In one camp (A) 930 young men were examined, in the other camp (B) 4,143 young men. The results are given in the accompanying table.

Calcified primary foci and similar glandular tubercles are not included in the table. Among "pleural conditions" are reckoned the most unrelated types of adhesions and other anomalies under "other miscellaneous conditions" are grouped cases of minor bronchopneumonia, insignificant cordlike scarred fields and so on.

The positive results appear relatively trivial, since in only 0.86 per cent and 0.67 per cent respectively were tuberculous conditions established that could not be detected simply by the usual auscultation and percussion of the thorax. The figures are lower than those hitherto yielded by examinations of students and of soldiers. Several examinations of students revealed 0.8 per cent to be actively tuberculous, nearly double the proportion shown in the foregoing figures. An examination of the members of a detachment of artillery (that is, of a regular army group in which the men had enlisted for long periods) in 1932 disclosed 0.56 per cent of the men actively tuberculous, the proportion of open cases being 0.28 per cent of the active. Furthermore, a roentgenologic examination of 1,369 policemen

showed six open and seventeen healed cases of the disease, in other words, 1.68 per cent of clinically undetectable cases were shown to be present. It may be surmised from these last startling figures that but for the protracted unsuspected presence of carriers of contagion among their comrades many of these men might not have become infected with tuberculosis. The higher proportion for students, soldiers and policemen can be explained by the fact that the average age of the two last named groups was above 21 years, greater for the most part than that of the youths of the work camps. According to the most experienced of the group examiners it is precisely in the older age classes that one encounters the very conditions the detection of which forms the principal objective of group examinations.

The data were further augmented by another report of the roentgenologic examination of a group. In this instance the clinical examination undertaken previous to the roentgenologic

Tuberculosis in Work Camps

	Camp A		Camp B	
	Cases	Per centage	Cases	Per centage
Active pulmonary tuberculosis	4	0.43	13	0.31
Cases of open tuberculosis	2	0.22	5	0.12
Inactive cases	4	0.43	15	0.36
Pleural conditions	5	5.0	76	1.80
Other miscellaneous conditions	51	5.5	23	0.56

had for the most part failed (in contrast to the foregoing figures for camps A and B). The youths hailed from the same region as those of camp B and were likewise candidates for the work service, but for the volunteer service in the years 1933 and 1934 (work service is today compulsory). Among a total of 1,567 men there were nine cases of active tuberculosis (0.57 per cent), three open cases of tuberculosis (0.19 per cent) and twelve cases of inactive tuberculosis (0.77 per cent). The total number of men presenting pathologic tuberculous conditions was accordingly twenty-one (1.34 per cent of the candidates).

All these data clearly demonstrate the importance of the group roentgenologic examination of youthful campers.

Research on the Alteration of Ferments in Syphilis

Professor Marchionini of the Dermatologic Clinic of Freiburg-in-Breisgau has sought to improve the diagnostic methods for syphilis by research on ferments. (Berta Ottenstein was his assistant in this work until the well known laws against non-Aryans forced her to leave her post.) The investigations have yielded noteworthy results. The alterations in the ferments were first studied as manifestations of chemical transformation within the skin of syphilitic subjects. The skin of the back of a hand of a healthy person was exposed for five minutes to the action of 5 cc of water contained in a bell jar which covered 5 sq cm of skin surface. The presence of various ferments could then be detected in this cutaneous dialysate: diastase, peroxidase and in exceptional instances, arginase. The same cutaneous experiment undertaken with syphilitic subjects elicited important variations from the ferment economy of the normal subject: an increase in diastase was noted; peroxidase disappeared completely and arginase, so seldom encountered in normal subjects, appeared with regularity. It appears therefore that the skin undergoes profound alterations during its attempt to ward off the spirochetes and their toxins. In addition these modifications may also probably be interpreted as indicative of visceral involvement. The increased value of the arginase in particular bespeaks a process in the cutaneous areas that compensates for the loss of arginase by the liver as a result of spirochetal activity.

The ferments in the cerebrospinal fluid also were studied. In syphilitic subjects there was no characteristic alteration in the arginase content but diastase underwent a manifest decrease even to complete disappearance, peroxidase, on the other hand, exhibited a substantial and well nigh regular increase. The observations in the cerebrospinal fluid were thus precisely the reverse of those in the cutaneous dialysate, which led Marchionini to conclude that the spirochetes and their toxins may exert an entirely different type of influence on the chemistry of the central nervous system.

Further experimentation proved that it is actually the spirochetes and their toxins that induce the foregoing extensive alterations in the chemistry of the ferments. In addition to the data on living subjects, analyses of the brains of deceased paralytic persons exhibited almost without exception a complete absence of diastase in those areas which had been most affected, notably the cortical region of the forebrain. Similarly living spirochetes obtained from tissue juice in the cutaneous nodules of syphilitic subjects during the first months of the illness were regularly observed to destroy completely the diastase content of normal cerebrospinal fluid. All these experiments were submitted to checking by necessary controls.

These methods of determining the presence of ferments are based on sensitive reactions and they can be of service to practical diagnostics. The foregoing ferment alteration in the cutaneous dialysate is apparent in the first weeks of syphilis before the Wassermann reaction has become positive and can be demonstrated at every stage of the disease, including the late period. Further, it is more sensitive than the majority of methods for the detection of syphilis. The same thing may be said of the characteristic alteration in the cerebrospinal fluid; it too is already manifested in the earlier stages of the disease by a large proportion (as high as 70 per cent) of patients and also quite frequently in the later stages by patients in whom other methods of detecting the syphilis have failed. Marchionini emphasizes that, in addition to technical improvements in the diagnostic procedures, follow-up examinations should be instituted in a greater number of specializing clinics.

ITALY

July 31, 1936

Medical Conventions

The conventions of the medical societies "Gruppo cardiologico italiano" and "Gruppo per lo studio del ricambio" have recently taken place at the medical clinic of the University of Milan. At the meeting of heart specialists, Professor Foa spoke on physiopathology of the vasosensory zones. The results of experiments carried out in this field are conclusive. The fact that arterial hypertension and hypotension originate in hyperesthesia and hypesthesia, respectively, of the carotid zones is beyond question. Many factors, among which are the conditions of the renal circulation and the postural changes of the individual, take part in the production of reflexes. The vagal and sympathetic nervous systems are also reflexogenic factors of importance. The speaker however does not admit the theory of Danielopolus autotropism. Many a fact that has been proved by experiments cannot be applied to the clinical field in relation either to the diagnosis or to the treatment of certain pathologic conditions. In this connection the speaker does not agree with Professor Pandes' advice of sectioning the splanchnic nerve in the treatment of arterial hypertension.

Professor Benedetti spoke on the methods proposed for quantitative evaluation of the morphology and functions of the heart. The speaker made determinations of the form, position and size of the heart of 300 men and 300 women by means of roentgenograms taken in anterior, posterior and lateral views with application of Viola's serial method. From the study of

the several diameters he made an index which represents the functional cardiac value. There are types of deformations of the index to show mitral stenoses, mitral insufficiency and aortic insufficiency; there are other types of deformity in pluvial valvular heart diseases, showing the existence of equilibrium between aortic and mitral insufficiency or the predominance of aortic insufficiency over mitral insufficiency and vice versa. In arterial hypertension the enlargement of the left ventricle can be seen only in the lateral view. In roentgenograms of patients suffering from exophthalmic goiter the left ventricular contour appears enlarged and the left middle arch of the roentgenogram appears prolonged or, rather, there is an increase of the left ventricle. According to the speaker, Viola's cardiac index which consists in calculating the frequency of the pulse and of respiration after performance of ten movements of flexion of the body and a running of 150 meters in eighty seconds is of great value in the clinical study of the functions of the heart and also in making determinations of the arterial pressure and in taking electrocardiograms. For quantitative evaluation of the functions of the heart in patients who are unable to run and climb stairs, the following method can be used: performance of rhythmic elevations of the extremities both in natural conditions and carrying certain weights. Professor Pace pointed out the danger of the test of carrying weights which can cause serious accidents in certain patients suffering from heart diseases.

At the meeting of physicians specializing in metabolic diseases Professor Quagliarello of the Naples University explained the transformations of the lipids in the body, the organs concerned with transformative processes and, especially, the intermediate metabolism. The speaker and his school found by extensive researches that the endocrine glands, especially the hypophysis, play an important part in the processes related to the fat metabolism and that the latter is related with the metabolism of the proteins and of the carbohydrates.

Professor Zola spoke on the treatment of diabetes in ambulant patients. The theory that hyperglycemia originates mainly in disturbances of the islands of Langerhans still stands although it is modified in the sense that the dysfunction of the islands of Langerhans is always associated with dysfunction of other organs. Because of the fact that the pancreas is the main pathogenic factor of diabetes mellitus, the disease can be considered as a uniglandular disturbance with pluriglandular reflexes. Satisfactory results in the treatment of the disease are obtained only by diet and by injections of insulin. The latter substance administered by mouth, and the commercial preparations known as antidiabetics, lack efficiency in the treatment of the disease. Recently the percutaneous route has been used for administration of insulin, but conclusions as to the results cannot as yet be drawn. Insulin protamine is now in use in some countries, especially the United States, but its use has not been as yet introduced in Italy. The ambulant treatment can be used more frequently than it is actually used. Many patients are treated in this form at the clinic of Milan.

Welfare for Mothers and Children

The statistics of the national organization Opera nazionale per l'assistenza alla maternità e all'infanzia which is concerned with the public welfare of Italian mothers and their children, show that the number of cases cared for in 1935 was 46 per cent higher than in 1934. The antepartum and postpartum care of mothers and their babies has been intensified. The number of centers for the protection and assistance of mothers and their children increased to a total number of 9,404 up to December 1935. Special courses of puericulture for physicians and midwives as well as courses for nurses paid for by the national organization have been established. The number of mothers and children who were under care of the organization during

1934 and 1935 was 1,713,978. The number of treatments given during 1934 and 1935 was 3,686,220. The donations given to the organization in 1935 amounted to more than a million dollars.

Number of Workers in Medicine

Recent statistical studies have shown that the number of persons practicing medicine or working in fields connected with medicine and its branches in Italy is as follows: 35,651 physicians, 12,912 pharmacists, 4,174 veterinarians, 15,982 midwives and 6,909 nurses. Of the total number of physicians, 9,390 are municipal physicians. From a comparison of the present statistics with those made in 1927 it is seen that the number of physicians increased by 5,567; that of pharmacists by 359 and that of veterinarians by 559. The number of midwives is almost unchanged.

Cataract and Dinitrophenol

Van der Hoeve and Polak-Damels have published a warning in the *Nederlandsch tijdschrift voor geneeskunde* against the dangers of dinitrophenol. The authors describe a case observed by them, of cataracta matura of both eyes resulting from absorption of some 40 Gm of dinitrophenol. The drug had been absorbed in the course of two distinct periods and at no time had the normally prescribed daily dosage been exceeded. From April 1934 to June 1934 the patient swallowed a capsule of 100 mg three times a day, a total for the period of 225 Gm; then from September 1934 to January 1935 an additional total of 18 Gm was absorbed. The initial symptoms appeared in June 1935, several months after the patient had ceased to use the drug. There was no other possible explanation for the development of the cataract.

Tropical Diseases in the Indies

Speaking at the University of Amsterdam, Dr. Brug discussed the present state of tropical pathology in the Dutch East Indies. He pointed out that few of the tropical maladies encountered in the Indies are autochthonous and that an understanding of the reasons for this is necessary if all possible avenues by which the diseases might be introduced into these colonies are to be brought under surveillance. The explanations are complex. Certain tropical diseases could never be imported into the Indies—African sleeping sickness (Congo trypanosomiasis) is an example in point. This disease is transmitted exclusively by the tsetse fly and this insect as well as the disease are not to be found outside Africa.

Schistosomiasis is found in Asia, Africa and America but not in the Dutch East Indies or Australia, because the species of snails that act as host is lacking. Certain other verminous diseases are unable to gain a foothold in the Indies because the living habits of the people protect them against such infection. Dracunculiasis (the disease caused by *Dracunculus medinensis*) is found only among populations who drink polluted and stagnant water, whereas the inhabitants of the Dutch colonies avoid such contamination. Clonorchis and the Paragonimus (or lung fluke) attack only eaters of raw or nearly raw fish, but uncooked fish is not eaten in the Dutch Indies. Yellow fever is not found there; the lightly clad population is not infected by fleas. To date *Loa loa* and *Onchocerca* have not been imported into the Indies. The reasons for the absence of kala-azar and yellow fever are not known.

The precise manner in which kala-azar is transmitted is not yet understood, but this cannot be said of yellow fever. The latter disease prevails over a great part of Africa but has not yet spread to the East Coast. The infected mosquitoes, however, can be transported great distances by the airplane.

Marriages

FRANKLIN STAFFORD WEARN, New York, to Miss Mildred Field King of Jackson Heights, Long Island, N. Y., June 27.

ERNEST CARL MARGARET, Glenwood, Iowa, to Miss Violet E. Hansen of Oakland, Calif., in Council Bluffs, Iowa, June 3.

LAWRENCE N. WATIER, Atkinson, Ill., to Miss Madeline Goering of Walcott, Iowa, in Davenport, Iowa, June 6.

RICHARD HARPER WHITAKER, Kernersville, N. C., to Miss Martha Louise Hubbard of Marshallton, Pa., June 17.

SHERMAN S. GARRETT, Champaign, Ill., to Miss Virginia Harley of Kansas City, Mo., Carlinville, in June.

HENRY FREDERICK STEPHENS to Miss Mary Emma Van Benschoten, both of Providence, R. I., July 7.

JOHN CRAWFORD HOLMAN JR., Franklin, Texas, to Miss Margaret McKinzie of New Orleans, June 20.

JOHN F. STRECKER to Miss Winifred Smith, both of Providence, R. I., in Fall River, Mass., June 20.

GEORGE GIBSON MOORE, McColl, S. C., to Miss Bonner Lipscomb of Ninety-Six, at Clinton, in July.

CHESTER E. HABERLIN, Stratford, Conn., to Miss Marian Kathryn Page of Bridgeport, June 11.

ROGER F. SONDAG, East St. Louis, Ill., to Miss Mary Jo Gualdoni of Murphyboro, June 30.

FRANCIS KEITH BRADFORD, Chicago, to Miss Margaret Anne Bowles of Richmond, Va., recently.

GEORGE L. JONES, Wanamaker, Ind., to Miss Martha Elizabeth Piel of Indianapolis, June 20.

LOREN LEONOTH LOVE, Valer, Ill., to Miss Thedis Wente of Johnston City, in Benton, recently.

JAMES A. ROBERTSON, Brooklyn, to Miss Cecile Florence Burns of Ossining, N. Y., June 27.

JOHN BERNARD CHRISTIE, Champaign, Ill., to Miss Marie Anna Sturdy in Peoria, in July.

LELAND MANN JOHNSTON to DR. HELEN MOORE PRESLEY, both of Nashville, Tenn., June 27.

RALPH KENNETH SHIELDS, Bethlehem, Pa., to Miss Mildred Mary Lyle of Columbia, June 20.

PHILIP FREDERIC SCHNEIDER to Miss Kathryn Ann Lantz, both of Evanston, Ill., June 17.

JOSEPH A. ROBINSON to Miss Elizabeth Arnold White, both of Bluefield, W. Va., recently.

FRED GRANT PEGG to Miss Pauline Amanda Sink, both of Winston-Salem, N. C., July 4.

SETH M. B. SMITH, Wausau, Wis., to Mrs. Elsa Kircher of Hollywood, Calif., June 22.

EDMOND L. RICE Soochow, Kiangsu, China, to Miss Mary O. Holler of Shanghai, June 29.

OVER SECKINGER GROSS, Vidalia, Ga., to Miss Bill Jones of Ludowici, in Alma, July 12.

ROBERT EDWARD TIMBERLAKE to Mrs. Johnnie R. Smith, both of Richmond, Va., June 29.

ROBERT FISKE WARREN to Miss Lucy Marie Sinclair, both of Brooklyn, July 2.

JOSEPH P. WILD, Hancock, Wis., to Miss Cecelia Wolf of Kaukauna, June 20.

OLIVER M. LAYTON to Miss Ruth Murphy, both of Fond du Lac, Wis., recently.

JOHN A. THRAWON to Miss Josephine Price, both of Milwaukee, July 11.

GUSTAVE F. WEBER to Miss Shirley Scales, both of Marshall, Texas, recently.

WILLARD W. WILD, North Charleston, S. C., to Miss Christine Daniel, June 6.

GEORGE M. WATT to Miss Dorothy Mattern, both of Cleveland, in July.

EDWARD J. SMITH to Mrs. Susie McCranie, both of Hahira, Ga., recently.

AUGUST FINCKE to Miss Emma M. Wagner, both of Brooklyn, June 30.

FREDERICK STEIN to Miss Harriett Stricker, both of Chicago, August 16.

HUGH J. HALL, Providence, R. I., to Miss Helen Thompson, June 28.

Deaths

Henry Parker Newman, professor of gynecology, emeritus at the University of Illinois College of Medicine, Chicago, died, September 21 of coronary occlusion, at his home in San Diego, Calif. aged 82. Dr. Newman was born in Washington, N. H., Dec. 2, 1853. He obtained his preliminary education at the New London (N. H.) Literary and Scientific Institution and later attended Dartmouth College. In 1878 he received the medical degree from the Detroit Medical College, and later, for two years studied at universities in Bonn, Leipzig and Strassburg. In 1880 Dr. Newman located in Chicago. He became professor of obstetrics and clinical gynecology at the College of Physicians and Surgeons of Chicago, of which institution he was also treasurer and member of the board of directors. At one time he was professor and emeritus professor of gynecology at the Chicago Polyclinic and one of the founders, president and professor of gynecology, Post-Graduate Medical School and Hospital of Chicago and was president of the laboratory of experimental research while it was part of that institution. From 1894 to 1904 he was treasurer, chairman of the Section on Obstetrics and Diseases of Women from 1900 to 1901 and a member of the House of Delegates from 1916 to 1918 of the American Medical Association. He was an Affiliate Fellow of the American Medical Association at one time vice president of the Chicago Gynecological Society, and one of the founders and a fellow of the American College of Surgeons. He was a member of the Gorgas Memorial Institute of Preventive Medicine, Washington, D. C., a founder of the *Congres Périodique International de Gynaecologie et d'Obstetrique* and in 1890 a delegate to the Tenth International Medical Congress in Berlin. He was consulting surgeon and gynecologist to the San Diego County and Mercy hospitals, San Diego, and the Scripps Memorial Hospital and Clinic, La Jolla. He established and was president and surgeon-in-chief of the Marion Sims Sanitarium was formerly on the staffs of the Chicago Post Graduate St. Anthony's, Chicago Maternity West Side and St. Elizabeth's hospitals, Chicago. In 1894 he was awarded the honorary A. M. degree by Dartmouth College.

Francis Joseph Quinlan, Amawalk, N. Y., College of Physicians and Surgeons, Medical Department of Columbia College, New York 1878, member of the Medical Society of the State of New York, formerly emeritus professor of laryngology and rhinology at the Fordham University School of Medicine, New York, and the New York Polyclinic Medical School and Hospital at one time on the staffs of the City Hospital, St. Vincent's Hospital and the New York Foundling Hospital, New York and the Jamaica (N. Y.) Hospital, aged 83, died, July 24, of diabetes mellitus and arteriosclerotic heart disease.

Samuel Robert Cunningham, Oklahoma City Medical College of Indiana Indianapolis, 1899, professor of orthopedic surgery at the University of Oklahoma School of Medicine, member of the Oklahoma State Medical Association, American Orthopedic Association and the Clinical Orthopedic Society, fellow of the American College of Surgeons, aged 64, chief of the orthopedic staff, State University Hospital and Crippled Children's Hospital, consulting surgeon and head of the orthopedic department St. Anthony Hospital, where he died, September 7.

Charles B. Finefrock, Port Clinton, Ohio, Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster 1895, member of the Ohio State Medical Association, past president of the Ottawa County Medical Society, county health commissioner from 1920 to 1936, past president of the Northwestern Ohio Health Commissioners Association at one time member of the school board and county coroner, aged 64, died suddenly July 1 of coronary thrombosis.

Joseph Jeremiah Kane ♂ Binghamton, N. Y., University of Pennsylvania Department of Medicine Philadelphia 1903, past president of the Broome County Medical Society, fellow of the American College of Surgeons, member of the board of education and past president of the city board of health, on the staff of the Binghamton City Hospital, past president of the Broome County Tuberculosis Hospital Chenango Bridge, aged 57, died July 18, of chronic myocarditis and cerebral hemorrhage.

Laurence Stephen Otell ♂ Washington, D. C., Johns Hopkins University School of Medicine, Baltimore, 1925, instructor 1928-1930, assistant professor 1930-1933 and associate professor of radiology, Georgetown University School of

Medicine, 1933-1936, on the staffs of the Georgetown University Hospital and the Gallinger Municipal Hospital, aged 39, died, July 27, at his home in Bethesda, Md., of leukemia.

John Ryan Devereux, Chevy Chase, Md., University of Pennsylvania Department of Medicine, Philadelphia, 1897, veteran of the Spanish-American and World wars, at one time served as a captain in the medical corps of the U. S. Army and was connected with the U. S. Public Health Service, formerly instructor in medicine and clinical professor of medicine, Georgetown University School of Medicine, Washington, D. C., aged 68, died, July 2, of cerebral hemorrhage.

Leonard Pearsons Sprague ♂ Chateaugay, N. Y., University of Vermont College of Medicine, Burlington, 1906, past president of the Franklin County Medical Society, served during the World War, for many years president of the board of education and health officer of the village and towns of Chateaugay and Burke, member of the staff of the Alice Hyde Hospital, Malone, aged 56, died, July 14, of cerebral hemorrhage.

George Thornhill Harris, Madison Heights, Va., Kentucky School of Medicine, Louisville, 1898, member of the Medical Society of Virginia, for many years a member of the school board, and the county board of health, on the staff of the State Colony for Epileptics and Feeble-minded, Colony aged 60, died suddenly, July 16, of angina pectoris.

Percival J. Herman, Selinsgrove, Pa., Cincinnati College of Medicine and Surgery, 1876, member of the Medical Society of the State of Pennsylvania, past president and secretary of the Snyder County Medical Society, bank president, formerly county coroner and member of the state legislature, aged 84, died, July 15, of carcinoma of the prostate.

Jacob Polevski ♂ Newark, N. J., University and Bellevue Hospital Medical College, 1909, research associate in cardiology at the University of Pennsylvania Graduate School of Medicine, Philadelphia, attending physician and cardiologist to the Newark Beth Israel Hospital, aged 52, died, July 27, in the Johns Hopkins Hospital, Baltimore.

Dean Samuel Harrison, Yorkville, N. Y., Albany Medical College 1899, member of the Medical Society of the State of New York, formerly mayor, and school and village health officer of New York Mills, member of the staff of the Paxton Hospital, Utica, aged 61, died, July 25, of coronary occlusion and arteriosclerosis.

Henry Theodore Nippert ♂ St. Paul, Miami Medical College, Cincinnati, 1891, president of the Ramsey County Medical Society in 1916, formerly clinical instructor in medicine, University of Minnesota Medical School, Minneapolis, on the staff of the Ancker Hospital from 1903 to 1919, aged 68, was drowned, July 4.

Eugene Lindauer, Philadelphia, University of Pennsylvania Department of Medicine, Philadelphia 1898, associate in neurology at the University of Pennsylvania Graduate School of Medicine, on the staffs of the Graduate and Philadelphia General hospitals, aged 64, died, July 28, of coronary occlusion.

Jerome Milton Keys, Omaha, Eclectic Medical Institute, Cincinnati, 1882, at one time professor of principles and practice of medicine and dean of the faculty, Nebraska Medical College, Lincoln, aged 85, died, July 9, in the Lutheran Hospital of hypostatic pneumonia and cerebral arteriosclerosis.

Louis Martin Kalajian, Cranston, R. I., Boston University School of Medicine, 1936, aged 28, intern at the Mercy Hospital, Wilkes-Barre, Pa., where he died August 21 of rheumatic heart disease, acute pulmonary edema and bilateral pneumonia.

Austin A. Swope, Crawfordsville, Ind., Medical College of Indiana Indianapolis 1898, member of the Indiana State Medical Association, on the staff of the Culver Hospital, aged 68, died, July 17, of cerebral embolism and gastro-enteritis.

Clarence Alexander Hamill, Ligonier, Pa., Western Pennsylvania Medical College, Pittsburgh 1908, member of the school board, aged 55, died July 19, in the Latrobe (Pa.) Hospital, of acute myocarditis and perforated gastric ulcer.

Carl Albin Lofgren, Chicago, College of Physicians and Surgeons of Chicago School of Medicine of the University of Illinois 1902, aged 67, died, July 12, of diabetes mellitus.

Robert Wesley Lynn, Lethbridge, Alta., Canada, University of Toronto Faculty of Medicine 1909, aged 52, died, July 8, as the result of an automobile accident.

Joseph S. Thrallkill, Wood River, Ill., American Medical College, St. Louis 1883, aged 75, died June 30, of arteriosclerosis.

Correspondence

NATURE OF DOG BITES

To the Editor—In the interest of accuracy, a revision of Dr Morris's revision of Mr Terhune's statement (*THE JOURNAL*, September 5, p 809) seems necessary. Canines give a vigorous shake to a bite" is altogether too broad a generalization to apply to a genus purposely bred to such wide variations trained to immensely different modes of action. The quoted statement is true of the terrier breeds, which, seizing small animals such as rats and rabbits, give a shake to break the neck. In contrast, breeds such as the collie and wolfhound, equipped with long shearing jaws, give a swift slash and leap back instantly to escape the enemy's riposte. Then consider the retriever breeds, trained to seize their prey with the utmost gentleness. I have never known one of this breed, even under extreme provocation, to give a human being a bite that could be called more than a reproachful nip. And again there is the bulldog trained to close his jaws on a victim and keep them closed with the grim implacability of a steel clamp. The bites of lap-dogs, with their small mouths and sharp teeth, resemble cat bites.

Besides the wound variation due to such instinctive modes of attack, one has to consider further variations due to each individual animal's personality or temperament. This factor probably varies more widely in dogs than in any other animal except man. The only conclusion is: Dog bites are as you find them, which will be in great variety, each indicating its own best mode of treatment.

JOHN G. HANNA, Dunedin, Fla

"SERUM TREATMENT OF ACUTE POLIOMYELITIS"

To the Editor—It has been generally overlooked that the advocacy of convalescent serum in therapy was probably based on a misconception. Because convalescent serum neutralized poliomyelitis virus in vitro, it was assumed that it would do so likewise in patients, without considering the time interval and the probable fixation of virus in the nervous tissue. In practically every region where poliomyelitis prevails, the disease was first recognized after paralysis had developed, and only later was it realized that diagnosis was possible during the preparalytic phase and that there was also a nonparalytic type. When serum treatment was instituted the results seemed almost uniformly favorable, since the ratio of the preparalytic to the nonparalytic could not be determined prior to treatment, nor could there be reliable knowledge of the incidence of unreported illness in the community that might have been due to unrecognized nonparalytic poliomyelitis.

Harmon's review, to which reference is made in the editorial on serum treatment of acute poliomyelitis (*THE JOURNAL*, August 8, p 432), can hardly be held as giving support to serum therapy except on clinical impression, and his final paragraph reads, in part, like an uncritical anticlimax to an exhaustive analysis. Jensen states in his report that it was the first time that serum was used in Denmark in preparalytic cases prior to 1933 only paralytic cases were reported. The recent review published by the Health Section of the League of Nations (R. E. 180, No 10-12 [Oct-Dec.] 1935) in commenting on Jensen's report points out that the patients treated early with such apparent success must have included not only severe cases but also all the mild cases, which would in any event have escaped paralysis, whereas, the cases treated later, since the attack lasted longer, included the severe cases and, therefore, would naturally show a higher percentage of paralysis.

But aside from considerations of the literature, my own experience has led me to doubt the efficacy of serum. In 1924

I had an opportunity to observe personally in the Syracuse outbreak (*THE JOURNAL*, Aug 11, 1928, p 394, *Am J Dis Child* 41 829 [April] 1931) a series of forty-six preparalytic cases, thirty-two of which were treated with convalescent serum and fourteen with horse serum possessing no antiviral properties. In the first group, 84 per cent escaped paralysis, in the second, 64 per cent. Analyzed statistically, it can be shown that there is no significant difference between the results in these two groups. Yet Kellogg (*THE JOURNAL*, Dec 21, 1929, p 1927) and others in referring to this observation inferred that both serums were effective, without inquiring into the natural history of the disease in such cases. Harmon has since collected the statistics on 531 untreated patients with preparalytic poliomyelitis and found that 380, or 71.5 per cent, never had paralysis at any time, and he points out that the outcome in patients treated in the preparalytic stage does not differ from the average of untreated patients.

Following Park's study in 1931, my associates and I began venturing to treat early cases of poliomyelitis without serum. In the 1935 outbreak in Syracuse, there were thirty local cases and five cases imported from neighboring areas. Of the thirty-five cases, twelve were reported after paralysis had developed and twenty-three were reported early in the disease without any muscle weakness. I was able to observe these cases carefully and had all but six in my service in the City Hospital. Omitting three cases in which serum was administered and two treated by spinal drainage, eighteen are left that were treated expectantly. Slight muscle weakness developed in two of these and sixteen of the patients remained nonparalytic.

It may be that a final decision cannot be made at this time. A number of recent papers have emphasized the value of transfusion in poliomyelitis. I have given transfusion in severe progressing cases and have seen apparent sudden cessation of the advancing paralysis and definite clinical improvement, but I have been inclined to attribute the improvement to the general and nutritional effects of the transfusion rather than to specific antibodies that the blood might have contained.

The chief objection to recommendation of serum treatment is that it makes it almost impossible to carry out observations on the natural history of the disease during epidemics. When I asked some Swedish pediatricians in 1930 why they had not obtained control series, they replied that they had not dared to let children with early poliomyelitis go without serum so long as it was considered valuable in therapy. This attitude likewise tends to induce anguish in parents whose children do not receive this treatment.

Finally, I should like to submit that the term "preparalytic" is inaccurate, in the sense that it is ordinarily used, as applied to cases in which there is no muscle involvement when first recognized. It would be far more accurate to speak of them as incipient poliomyelitis cases, denoting that they might remain nonparalytic or terminate in muscle weakness or paralysis.

A CLEMENT SILVERMAN, M.D., Syracuse, N. Y.

DENTAL NOMENCLATURE

To the Editor—The first book to be reviewed in *THE JOURNAL* August 15, page 527, is *Dental Roentgenology*, by Dr LeRoy M. Ennis the second edition. It is well reviewed with the exception of the last sentence, which reads:

As in the first edition the author clings to certain terms that are obsolete and should be changed: he uses the term premolar instead of bicuspid and refers to mandibular and maxillary molars instead of upper and lower molars.

Most of the few dentists who read *THE JOURNAL* will merely pass this by and remark inwardly that nothing can be done about it, with a smile, but, for the medical man who wishes to inform himself intelligently on anatomic matters let him not

be misled by the statement quoted. He will find in a certain little book, *Dental Anatomical Terminology*, by L. Pierce Anthony for the Committee on Nomenclature of the American Dental Association, and published by the committee in 1930, that premolar mandibular and maxillary are the terms of choice and not bicuspid, upper and lower. Some one other than Dr. Linnis seems to be out of date.

LAWRENCE CURTIS, D.D.S., M.D. Philadelphia

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS, BUT THESE WILL BE OMITTED ON REQUEST.

HYPERPYREXIA IN TABETIC FORM OF DEMENTIA PARALYTICA

To the Editor—In the treatment of the tabetic form of dementia paralytica when should hyperpyrexia be attempted and what is the best recognized method? Where can I find literature on this subject? Kindly omit name and address.

M.D. Pennsylvania

ANSWER—The earlier a case of the tabetic form of dementia paralytica is treated with hyperpyrexia the better are the chances for a recovery. Hyperpyrexia will in certain cases arrest the disease and produce a mental remission in the patient. This treatment cannot, of course, restore nerve tissues that have already been destroyed, though it may decrease the inflammatory infiltrations that are caused by the disease. It may also kill some or many of the spirochetes present in the tissues of the central nervous system if the fever is high enough and sustained long enough. To be effective in this sense, a bout of fever should be sustained for at least eight hours above 103.5 F. and above 105.8 for two of these eight hours. Between ten and twenty or more bouts of fever should be given each patient.

There are many methods in use for producing artificial fever and opinions differ greatly as to what modality should be employed. The oldest methods are those which use malaria typhoid vaccine and injections of foreign proteins and chemicals. Since 1929 a number of physical agents have been recommended by various authors for the production of therapeutic fever in man. Among these are hot baths and external and internal heating devices. Hot baths are used only by a comparatively small group of physicians because they are reported to be inherently more dangerous than the other methods. External heat in the form of electric blankets, electric light cabinets, radiant heat cabinets and air conditioned cabinets has been recommended by certain groups of investigators. Other workers prefer the use of penetrating heat produced by diathermic currents, so called short radio waves and electromagnetic induction. It is quite impossible, therefore, to state that any method is a recognized method for producing artificial fever. The entire subject is at present in a flux. Changes in the methods of treatment are being advocated constantly. The literature on this subject is scattered throughout the medical journals of the world and no comprehensive book has as yet been written on the subject. The best way to become acquainted with the writings of hundreds of men who are interested in the subject is to consult the *Cumulative Index Medicus*.

Hyperpyrexia is at present a hospital procedure and should not be attempted ambulant or in the office of a physician. The successful treatment of a patient with artificial fever depends more on the skill of the physician than on the use of any specific drug, disease or machine. It is much more important, therefore, that a physician be well schooled in his particular method for producing elevated temperatures than that a certain definite method of inducing fever should be chosen. Many of the machines now on the market are unjustly extolled by their manufacturers. Certain machines have been approved by the Council on Physical Therapy and will produce fever efficiently. Others leave much to be desired in their action and some are dangerous. It is therefore much more a question of the skill and experience of the physician who uses artificial fever therapy than a question of the modality he chooses to employ.

GLEET

To the Editor—A dentist married one year developed a urethritis three and one-half months ago. There is no history of outside sexual contacts. No contraceptives are being used by either husband or wife. The urethritis was rather mild, the discharge being grayish white and mucopurulent. This lasted about three weeks and subsided. Repeated examinations failed to show gonococci. Now after three and one-half months the walls of the terminal part of the anterior urethra as well as the meatus are often glued together; there is a slight amount of discharge (small drop) in the morning. The urine is not cloudy, grossly even in the first glass but always shows clumps or flakes of pus floating in the urine. The second glass is always entirely clear. Except for the anterior urethritis the examination of the genito-urinary system is negative. The patient is in the best of health, without evidence of tuberculosis anywhere, including the genital apparatus and the prostate feels normal. My diagnosis was nonspecific urethritis. My treatment consisted of occasional injection of mild protein silver 10 per cent, occasionally potassium permanganate 1:5000, 3 per cent resorcinol several times and on two occasions diluted hydrogen peroxide followed by mercuric oxycyanide 1:800. The chronic urethritis still persists. Kindly diagnose and outline treatment. Louis A. Rubin, M.D., Orr, Minn.

ANSWER—The patient's problem concerns itself with the determination of the cause of the morning drop and the glued meatus. This condition is sometimes called "gleet."

One of the common causes of gleet is the presence of infection in the prostate gland or seminal vesicles or both. Therefore a careful examination of the prostate should be made by rectal examination and the prostate and vesicle carefully massaged and the fluid examined for the presence of pus. If pus is found, the fluid should be stained with methylene blue and a Gram stain made to identify the organisms present. It probably will be advisable to make cultures of the fluid. If possible, a bouillon filtrate should be prepared and the patient inoculated with it. Heat by rectum, sitz baths and massage are in order should these organs be involved.

Careful exploration of the urethra should be made with acorn bougies to ascertain the presence of granulations or strictures. Should they be found, sounds should be passed at weekly intervals and the urethra should be massaged on the sound. This should be followed by the injection of strong protein silver 0.5 per cent, or urethral irrigation may be used with potassium permanganate in the strength of 1:4500.

In rare instances the discharge may be due to a small meatus. If this is the case a meatotomy should be done.

Finally, if all these are negative, examination of the urethra with the endoscope is advisable in order to see whether infection in the glands of Littre or in the Lacunae of Morgagni is present. This should be treated by fulguration with the high frequency spark through the endoscope.

TOXICITY OF OSMALITE TERMITE REPELLANT

To the Editor—There is a preparation named Osmalite used in the preservation of wood. I understand that its composition is dinitrophenol, sodium fluoride, potassium bichromate and gum arabic. This preparation penetrates into rubber gloves and the skin of the hands is stained a deep yellow. It is applied as a paste with a brush to poles and a week ago one of the workers came in with a folliculitis which I felt might be traced to this compound. Have you any record of industrial poisoning due to this specific compound used in the manner described?

J. D., Michigan.

ANSWER—Osmalite is a fairly new wood preservative so that full knowledge of its toxic properties is not available. Its chief use is said to be as a repellent for termites. It is believed to contain the following constituents in approximately the proportions shown: dinitrophenol 14 per cent, sodium fluoride 78 per cent, potassium bichromate 3 per cent, gum arabic (acacia) 5 per cent. This substance is mixed into a paste, approximately one pound of water being used for two pounds of the powder. This paste is destructive for protective gloves so that contact with the skin is a reasonable expectancy. In addition to local action, systemic involvement conceivably may arise from skin absorption (chiefly of the dinitrophenol which readily passes through the skin), and possibly through carrying particles of the chemical mixture from the hands to the mouth in eating or smoking.

Each of the ingredients thought to be present has been the source of skin disease. In addition the dinitrophenol in small quantities is regarded as highly toxic in that well defined systemic disorders may be produced. These have been well described in *THE JOURNAL* during recent months in connection with the use of dinitrophenol in weight reduction. The action of this substance as a skin irritant is quite like that of trinitrophenol (picric acid). Sodium fluoride may be accepted as relatively unimportant as a skin irritant but cases have been described. This substance is currently attracting attention as a source of damage to the teeth. Even in the low percentage

present, potassium bichromate may be injurious to the skin particularly if the integument should be broken. Dermatoses from gum arabic are probably allergic in nature.

A folliculitis from osmirite is not denied as a possibility, but it is felt that a direct contact chemical dermatitis is more likely. No known published records have reported a dermatitis from this wood preservative, but casual inquiry of users indicates the occurrence of skin disturbances.

In the absence of extensive toxicologic data it becomes necessary to regard this chemical mixture (because of extensive information about its constituents) as dangerous if in fact it is brought directly in contact with the worker's body.

INSOMNIA IN DIABETES

To the Editor—An intelligent white man aged 29 has had diabetes for the past five years. He complains that for the past three months he has not been able to sleep except for intervals of from fifteen to thirty minutes. He says that he is tired but is never sleepy. I have given him practically all the recognized hypnotics from bromides in massive doses, to pentobarbital sodium, but they do not seem to be effective in producing sleep. At the present time his diabetes is being treated with 60 units of insulin and a diet containing 125 Gm of carbohydrate. His blood sugar level seems to be lowered under this treatment being 200 mg at the present date. His urine is acetone and sugar free. He maintains his weight at between 140 and 146 pounds (63.5-66 Kg.). His blood pressure is 130 systolic 80 diastolic. His pulse rate varies from 100 to 120 and the respiration rate is 18. During the past two months he has had a rapid pulse of from 100 to 120 per minute even at rest. At times he gets attacks of palpitation of the heart which do not last very long. His past medical history is practically negative. There are no complaints referable to the genito-urinary or gastro-intestinal tracts or other symptoms except as stated. At times he breaks out with an urticaria which he thinks may be due to the insulin since it often occurs after he injects the insulin prescribed. What is the apparent cause for his sleeplessness and how can it be treated? Can insulin in large doses be responsible in any way? Can insulin cause an urticarial reaction? Please omit name.

M D Pennsylvania

ANSWER—Diabetic patients seldom have insomnia. Of course there is the possibility that the patient may develop a low blood sugar during the night even though the blood sugar reported is 200 mg. This should be followed up more closely. Insulin does not cause insomnia without accompanying symptoms, such as those resulting from hypoglycemia. Therefore in this patient one must look for other reasons. By chance is there hyperthyroidism? Does the patient take other drugs? Is the Wassermann reaction negative? A lumbar puncture might be desirable and a nervous cause should be sought. Is the patient neurotic? Does he earn his own living?

As for urticaria, it is true that allergic reactions do develop in patients after administration of insulin, but as a rule these disappear within a few weeks of the beginning of treatment. When they once disappear, they seldom recur.

REMOVAL OF PIGMENT FROM SKIN

To the Editor—In the March issue of *Hysgia* there is an article entitled *The Blue Man* written by Arthur W. Stillians. He states that it is possible to remove silver deposits from the skin. The son of a prominent man in this city has a permanent "black eye." This dates to three years ago when the doctor who was in this office before me attempted to force silver nitrate through the tear duct causing the silver nitrate to go into the tissues and turn black. This has caused a permanent pigmentation of the skin about which the family is very anxious. Therefore I am writing to you to find out the technique of the method described in the aforementioned article. Just which photographic reducing fluid is used? What strength is to be used? How is it sterilized? Any other pointers in the technique, such as depth of injection and advisability of periods between injections will be appreciated. I should like to be able to help this child.

M D New Hampshire

ANSWER—The reducing fluid used for removal of silver from the skin is one composed of a solution of potassium ferricyanide and sodium thiosulfate in water. One per cent of the ferricyanide and 6 per cent sodium thiosulfate were found to be as efficacious as any other percentage though other strengths will do the work. A 2 per cent solution of potassium ferricyanide is prepared (10 cc is a convenient quantity) and a 12 per cent solution of sodium thiosulfate. Equal quantities of these two are drawn into the syringe just before injecting. If mixed and allowed to stand the solution oxidizes and becomes inert. As soon as the mixture is made, it is injected intradermally through a fine platinum needle causing a wheal. When this subsides after several days a white spot will be seen where the silver has been removed.

The injection causes a sharp stinging sensation. Local anesthesia may be used if epinephrine is omitted for it delays

drainage of the silver solution into the lymphatic vessels and the silver is redeposited. Nerve blocking can be accomplished by injecting the anesthetic into the infra-orbital foramen, though additional subcutaneous injections will be needed about the internal canthus. Unfortunately the skin of the lower lid, which is most often stained by silver, is the hardest part of the skin to treat because it is so thin. Great care must be exercised to place the fluid as superficially as possible. The needle should be very fine, and a locking syringe is of great advantage when many injections are to be made. If the solution is made in sterile distilled water in sterile glassware and handled with surgical precautions, the fluid needs no sterilization. Potassium ferricyanide is antiseptic, and attempts to sterilize will destroy the value of the solution.

There is no danger of poisoning from the use of potassium ferricyanide. So little can be introduced even by the fastest worker, and it is destroyed so rapidly by oxidation, that any harm to a human being from this source is unlikely.

It is advisable to allow the reaction in one area to subside somewhat before treating a contiguous area, though no harm to the skin has resulted from many thousands of such injections.

BILATERAL CAROTID ANEURYSM

To the Editor—Is there any treatment for bilateral carotid aneurysm? One side is $1\frac{1}{2}$ by 1 inch the other side 1 by three-fourths inch. They do not seem to have pedicles. If there is a treatment please give prognosis. Kindly omit name and address.

M D Wyoming

ANSWER—Treatment for bilateral aneurysm should be limited in adults preferably to open operation with obliteration of the sac and reconstruction of the lumen of the common carotid artery, or end to end suture if feasible. In young persons and occasionally in adults it may be found desirable or necessary under certain conditions to ligate the common carotid artery above and below the aneurysm. In a large percentage of adults this will lead to cerebral anemia and perhaps hemiplegia and symptoms of mental degeneration.

Before operation an effort should be made to develop collateral circulation by digital compression of the artery proximal to the aneurysm, and only one side should be operated on at a time. The metallic band as used by Halsted, Matas and Allen for either complete or partial occlusion of the artery has many advantages over ligatures. The lumen of the artery may be occluded in one or more stages as collateral circulation develops. It may be removed after partial or complete occlusion if cerebral symptoms develop.

Local anesthesia should be used because of the danger of cerebral anemia.

The prognosis without operation is poor, although cases of spontaneous thrombosis and cure of a common carotid aneurysm have been reported. There is considerable danger of a propagating thrombosis after ligation and but little after use of the metallic band.

In old or bad risk patients, no treatment other than rest and avoidance of effort should be attempted.

IRRITATION OF EYES FROM LACQUER SPRAY

To the Editor—I am practicing in a town where a radio cabinet factory is located and have had some patients consult me on the chronic irritation of the eyes due to the lacquer spray used in cabinet manufacture. I have consulted the literature on the subject and have not been able to find a definite treatment. I have used many of the common eye lotions to no avail and shall be grateful if you will kindly advise me on the subject.

M D Indiana

ANSWER—The coating materials customarily applied to radio cabinets are not dissimilar to those widely used in other industries including furniture and piano manufacture. The many possible lacquer solvents and thinners include toluene, xylene, benzene, petroleum fractions, divers alcohols and acetates. All are potential eye irritants. The direct entry of any of the fluids into the eye, such as from splashing, will inevitably lead to an acute conjunctivitis. More often the eye disorders are due solely to day by day exposure to vapors and mists created in the normal course of spray coating. This form of conjunctivitis is not severe but commonly will persist as long as exposure is continued, regardless of treatment. There is no specific treatment, and relief is to be sought in preventive measures. Properly designed spray booths protect the workman against this form of injury. Goggles are available with soft rubber edges which by fitting closely against the skin about the eyes, avoid the entry of irritants. Various types of hoods likewise offer some degree of protection.

In the absence of secondary infection, this form of conjunctivitis may be expected to disappear without or with treatment soon after exposure is eliminated. In many Indiana manufacturing cities large numbers of Kentucky mountaineers are employed. In this class of workers trachoma has been encountered and this constitutes somewhat of an industrial hazard in that state. Until ruled out, trachoma should be suspected in the present situation. Remotely the possibility exists that methanol (wood alcohol) may be used in radio cabinet coatings. This substance, if present obviously provides a greater threat to the eyes of exposed workmen than any usual constituent of paints lacquers, enamels or their thinners.

CAUSES OF DEATH

To the Editor—A man aged 48 employed by a local distributing company was involved in an automobile accident February 29 near an adjoining city. As a result of this accident he suffered what were considered several minor contusions about the body. He was taken to the office of a physician in that town where he was treated for his injuries. This physician states that the deceased was acutely intoxicated when he first examined him and that he treated his injuries and that he left his office apparently all right so far as the injury was concerned. He was taken in custody by the highway police and taken to police headquarters in the same city and soon after his arrival there suffered an apparent collapse and died in a comparatively short time. The body was brought here and I participated in an autopsy to ascertain whether or not he died of injuries or from natural causes. The brain was normal except for a slight gumma in the right parietal lobe. There was no hemorrhage of the brain or the meninges and no fracture of the skull. Contusions were present over the right eye over the bridge of the nose and on the left arm. There were contused abrasions over the tip of the left shoulder and over the anterior surface of the tibia about midway of both legs. The heart and lungs were normal. No enlargement of the heart valves was apparent. There was full compensation. The lungs were normal. No trouble existed with the aorta or large vessels. The abdomen was normal except for slight enlargement with an apparently fatty degeneration and some granular degeneration. There was fatty degeneration of the penis on which there was a scar from probable chancere on the dorsal surface. These conditions however were not sufficient causes for sudden death. In the stomach was a foreign body tightly embedded within the pyloric orifice at the outlet. Incision into the organ proved this to be a cork stopper from a vial or bottle. The cork measured 12 by 10 by 13 mm. No other solid contents remained in stomach. The man's family physician and the doctor who attended him for the injuries were both present at the autopsy. The family physician stated that the deceased had shown sugar in the urine for a considerable time. The doctor who attended his injuries verified the deceased's condition as acute alcoholic intoxication at the time of his injury. The question confronting us at present is whether this cork tightly embedded in the pyloric outlet could have been the cause of death especially in the presence of a stomach full of liquid as was apparently the case at the time of death and the existing diabetic condition.

M D Centralia Ill

ANSWER—There is no reason to assign any importance in causing death to the small cork found at the outlet of the pyloric orifice.

The record submitted does not warrant any conclusion with respect to the exact cause of death. The description of the abdomen is not clear—"normal except for slight enlargement of what? with atypical fatty degeneration and some granular degeneration." Question may also be raised with regard to the statement that the brain "normal, except for a slight gumma in the right parietal lobe. This is an unusual place for a gumma and one wonders whether the diagnosis of gumma is correct. The coronary arteries do not seem to have been examined which is unfortunate especially in view of the fact that the patient may have had syphilis. As matters stand acute alcoholic intoxication shock due to the injuries received and diabetic coma cannot be excluded as possible factors in the causation of death.

INCIDENCE OF EMBOLISM AFTER OPERATION

To the Editor—I have an inquiry at hand relative to the percentage incidence of emboli secondary to gallbladder operations with removal or only drainage and also as to the percentage incidence of emboli secondary to operations for acute appendicitis. If there are any further data as to the frequency of emboli necessitating amputation of a leg secondary to an alleged sprain of the ankle joint it would be of decided value to me. Kindly omit name.

M D Illinois

ANSWER—A paper by Earl F. Henderson (*Arch. Surg.* 15:231 [Aug.] 1927) entitled "Fatal Pulmonary Embolism" contains one of the largest collections of statistics on the subject. Briefly in one of the groups of cases which he studied there were 63,345 intra abdominal operations; these operations were performed at the Mayo Clinic between 1917 and 1926. In this series of cases in 11,689 operations on the gallbladder and ducts the incidence of fatal postoperative pulmonary embolism was 0.30 per cent whereas following 12,356 operations on the

appendix the incidence of fatal pulmonary embolism was 0.02 per cent. Emboli following cholecystostomy were not separated from those following cholecystectomy. According to K. K. Nygaard, among 165,000 cases in which operation was performed at the Mayo Clinic there were approximately 1,700 instances of postoperative thrombosis and embolism, either nonfatal or fatal.

REPEATED ABORTIONS AND STERILITY

To the Editor—A woman aged 28 married nine years desires to have a child. She had an induced abortion done in 1927 after a three and one half months pregnancy another induced abortion in February 1931 after a ten weeks pregnancy and another induced abortion in November 1931 after a five and one half months pregnancy. In June 1934 she had a spontaneous abortion after ten weeks. No contraceptives have been used by either her or her husband since the last pregnancy. Her menstrual period occurs every twenty four to twenty-eight days and lasts about four days. Some months she has more dysmenorrhea than others. She has had midmenstrual pains in the lower right quadrant almost every month since her appendectomy in 1925. Tonsillectomy was performed in 1928. The cervix was cauterized in 1935 and at present appears in good condition. The vaginal secretion and the cervical secretion react neutral to litmus. No masses can be felt in the adnexa. The uterus and cervix appear in good position. There is no history of venereal diseases. The Wassermann reaction is negative. The urine is normal. The blood pressure is rather low being 108 systolic, 60 diastolic. A month and a half ago she had a dilation and a curettement done by another physician who told her that it would help her. She is disappointed as she expected to become pregnant soon after. The woman appears normal and in good health to the best of my knowledge. Can you tell me why she is unable to become pregnant again after being very fertile during the years 1927 to 1934 inclusive? Will you suggest a line of treatment that I may follow? Would a tubal insufflation be indicated? What about endocrines in this case? Would a trial at artificial insemination be of any benefit? Kindly omit name. M D New Jersey.

ANSWER—The repeated abortions which this woman has had may be the cause of her sterility. There is no mention of the type of recovery made from the last abortion. Not infrequently even when there are no outward signs of infection following an abortion there may be a mild salpingitis or perisalpingitis sufficient to produce closure of the tubes. Before anything further is done it is advisable to examine the husband's semen to make certain that he is not the cause of the sterility. If the spermatozoa are normal, a tubal insufflation should be performed. It was unwise to perform a curettement without first being certain that the tubes were patent.

There is no indication for the use of endocrines in this case. If the tubal patency test reveals normal tubes nothing further should be done for at least a few months and the patient should be encouraged with the information that she and her husband are normal and that a pregnancy may therefore occur without special treatment. The patient is unreasonable to expect fertilization to follow within a month and a half after a dilation and curettement even if the tubes are open. These operations are by no means always followed by pregnancy and it is unfortunate that the physician who performed the curettement promised the patient too much. There is no need to resort to insemination of sperm at the present time even if the tubes are found to be patent. This procedure is a last resort and of course, is to be employed only if the sperm are normal and the tubes are patent.

EPILEPTIC SEIZURE IN MOTION PICTURE OPERATORS

To the Editor—A man who has been operating a moving picture machine for a number of years was brought to the hospital having an epileptic seizure and a clonic spasm in one of his arms. There is no previous history of any illnesses over a period of many years. He does not drink. His general health is good and he has never had such a seizure before. The spinal Wassermann reaction is negative. I am of the opinion that some poison coming from the operation of the machine in a poorly ventilated room might be responsible for the condition. I will very much appreciate any help you can give.

M D, Texas

ANSWER—A direct relationship between the work of a motion picture operator and the condition described in the query is improbable or at best may be established with difficulty. Some remote factors may be mentioned as possibly related. In some electric arcs such as may be used for motion picture projection traces of carbon monoxide may arise. Epileptoid seizures have been reported as a manifestation of carbon monoxide poisoning. In this event some more characteristic features of carbon monoxide asphyxiation should clearly be detectable. The high temperatures at times present in booths place a burden on the normal functioning of the body but epileptoid seizures cannot be regarded as an anticipatable result. In years past certain types of carbons used in arc lamps have been jacketed with metal to decrease the rate of burning. Metal vapors thus produced may cause "metal fume fever." In case

claim before a compensation board, lead poisoning from this source was asserted. It is the intent of this discussion to indicate that while the work of the motion picture operator may be associated with various undesirable work conditions, none are known causes of epilepsy.

TREATMENT OF SYPHILIS COMPLICATED BY FUNCTIONAL PRURITUS

To the Editor—A man aged 26 contracted syphilis in April 1934. At that time he came under the care of another physician who gave him a course of ten injections of nearsphenamine and ten injections of a bismuth compound intramuscularly. Following this two Wassermann reactions at monthly intervals were negative. In August 1934 while the patient was receiving treatment, he noticed a severe form of biting or burning subcutaneously distributed over the entire body. This burning or biting was of but a few seconds duration only to recur in from half an hour to three or four hours later. He presented himself to me in December 1934 from which time on he received approximately forty injections of nearsphenamine and forty injections of a bismuth compound intramuscularly. Up to the present time his sensation of biting and burning has been uninterrupted. Also at various times he has noticed tachycardia on retiring. A neurologic consultation revealed no pathologic changes due to syphilis. The consultant did make a presumptive diagnosis of either hypothyroidism or hyperthyroidism. A basal metabolic test revealed a minus 10. The iodides were given in dosages of seven drops three times a day without any amelioration of symptoms. Thyroid was given in dosages of one tenth grain (0.006 Gm.) four times a day with cessation of the tachycardia. Various drugs have been attempted with no relief. Urinalysis is negative the blood pressure and temperature are normal and physical examination is essentially negative. Anything you may be able to advise as to the future course of treatment for this patient will be appreciated. Please omit name.

M D Pennsylvania

ANSWER—In a man 26 years of age with burning and biting of the skin and no obvious cutaneous lesions, it would seem most likely that the complaint is of neurogenic origin. If the patient were 65 or older, the possibility of acarophobia would enter into consideration. The fact that he has received forty injections of nearsphenamine and forty injections of a bismuth compound without the development of cutaneous complications of any sort would indicate that the burning and biting were not the result of the original course of nearsphenamine and bismuth he received at the time the syphilis was recognized. The persistence of the symptoms during the rest interval from treatment strengthens this impression. The likelihood of an urticaria should be considered but apparently can be dismissed in view of the absence of any skin lesions. The same applies to infestation with scabies or other mites.

The development of a functional pruritus in this young man who recently acquired syphilis seems a plausible explanation for his complaint from the data given in the inquiry. If the blood and spinal fluid tests are now negative, two courses of a bismuth compound a year, fifteen injections each for the next two years, would seem warranted. In addition, the repeated reassurance that his infection is controlled and the administration of a sedative should dissipate his complaint.

RESIDUAL PARALYSIS AND ANESTHESIA OF FOOT

To the Editor—I have a patient aged 10 with a residual paralysis and anesthesia of the right foot. About five years ago when the child was attempting to learn to swim the large toe was cut. This wound did not heal and x-ray examination revealed a slight involvement of the periosteum. In October 1935 the wound healed but since then a large amount of callous formation has formed over the site of the old wound on the inside of the toe. An orthopedist prescribed shoes which do not relieve the condition. In walking the foot is everted and the toe greatly so that the site of the old wound is the part at the bottom. Many methods have been tried to keep the toe in position without any success. There is slight sensation and motion present now for the first time. Is there any way of keeping the toe in position?

C R CHANBORN M D Janesville Minn

ANSWER—Treatment in this case would depend to some extent on the etiology of the paralysis. Infantile paralysis rarely if ever produces anesthesia. Paralysis secondary to spina bifida may be of a mixed type with paralysis of some muscles and spasticity of others and quite commonly is associated with anesthesia. Lacerations, like trophic ulcers, in regions that are totally anesthetic, are characteristically slow in healing. Recurrent callous formation in the scar results from chronic trauma and can be relieved only by protection against the repeated injury. Reconstruction operations are contraindicated if the anesthesia persists, but partial return of sensation and muscle function would suggest that surgical stabilization of the foot be considered. This would tend to correct the eversion of the foot and the dragging of the toe in walking. Amputation of the toe in cases such as that described is justified if other measures fail to bring about healing.

ADMINISTRATION OF ANTITOXIN TO SENSITIVE PATIENT

To the Editor—I have a patient to whom it has been necessary to give a prophylactic dose of antitetanus serum on two occasions within the past year. The first dose was accompanied by some degree of urticaria but no untoward symptoms. The second dose given about three weeks ago produced fever (103 F) headache and violent pains in the knees and muscles of the calves. It was necessary to give morphine on several occasions to quiet the patient. My reason in writing is to ask your advice as to the advisability of using antitetanus serum following subsequent accidents if such occur. Undoubtedly this boy who is 8 years old will need prophylaxis again and it would be with some temerity that I would administer the serum. Can you suggest a procedure that would obviate the likelihood of the foregoing or similar reactions? Please omit name.

M D Ohio

ANSWER—Should it seem advisable to administer antitetanic serum to the patient on some future occasion, one of the following plans may be adopted:

1 Use cow tetanus antitoxin instead of horse tetanus antitoxin, provided the latter was given on previous occasions (There is a cow tetanus antitoxin on the market.)

2 Prior to serum injection, make a skin sensitivity test and, if positive, attempt to desensitize the patient. For the test, inject the serum intracutaneously in a dilution of at least 1 to 10. Do not attempt to make the tests with undiluted serum.

3 Before injecting tetanus antitoxin, add to it from 0.3 to 0.6 cc of epinephrine of a 1:1,000 solution.

PSYCHOTIC IMPOTENCE

To the Editor—I have a patient 45 years of age, apparently in good health whose only complaint is inability to have sexual intercourse. He is a man who has never had sexual contact with any woman but his wife who died about one year ago. His impotence dates from that time. Previous to this he had intercourse every night. He has sexual desire and appetite but is unable to obtain an erection with any woman although he has made several attempts with more than one woman. Often when he awakes in the morning and occasionally at other times he has a strong erection. He states that he is in love with one of these women and would marry again if he could have sexual satisfaction. I can find nothing wrong on physical examination. He has a normal prostate. Please omit name.

M D Michigan

ANSWER—The cause of this man's impotence is obviously psychic and requires a thorough, lengthy psychiatric study. It will be necessary to know a great deal about the man and his relations with his late wife and numerous other facts which are not mentioned in the question.

INJECTION METHOD FOR VARICOSE VEINS

To the Editor—A few patients have come to me with varicose veins and informed me that they have received injection treatments (of what they knew not) and to no avail and wish to know if any other form of therapy is available. When I mention surgery stripping the veins with excision they look askance and dubious. What in your opinion is the most serviceable agent to inject with the least reaction causing the percentage of sclerosis generally speaking? I realize that certain solutions are more adaptable to certain types of veins. As a last resort what agent would you say would give the highest percentage of sclerosis? What are its undesirable features? What are the reactions to it? What is the technique of its preparation and administration (if these are not obvious)? Thank you for any helpful suggestions in treating recalcitrant nonsclerosing veins.

DEE EDWARD FRANK M D New York

ANSWER—The questions asked by the correspondent embrace the entire subject of the diagnosis and treatment of varicose veins. These questions and some others have been answered in a small pamphlet issued by the committee on varicose veins of the American Medical Association and printed in 1931 in connection with the Detroit session. Such pamphlets are available through the American Medical Association.

Generally speaking, no one can successfully undertake the treatment of varicose veins without having visited a well organized varicose vein clinic of a university or general hospital and received first-hand information from men who are handling a large number of cases. This is the best way to avoid pitfalls and discouraging results.

DRUGS FOR RELIEF OF PAIN

To the Editor—Is there any drug or combination of drugs that may be given hypodermically which will relieve pain (severe) and which is not an opiate derivative? Please omit name and address.

M D California

ANSWER—The problem of a satisfactory hypodermic analgesic to serve as a succedaneum for an opiate in the treatment of severe pain has not been solved as yet.

Maryland June Examination

Dr John T O'Mara, secretary, Board of Medical Examiners reports the written examination held in Baltimore, June 16-19 1936 The examination covered 9 subjects and included 90 questions An average of 75 per cent was required to pass. One hundred and fifty-six candidates were examined, 138 of whom passed and 18 failed The following schools were represented

Interpretation of Laboratory Findings. By Raymond H Goodale M.D. Pathologist City Hospital Worcester Mass. Cloth Price, \$2.25 Pp 170 Philadelphia F. A. Davis Company 1936

This is a concise collection of facts regarding the usual routine laboratory tests and their interpretation. The first part is devoted to a brief discussion of the normal values and the interpretation of abnormal values of the various body fluids and excretions. The second part is an alphabetical listing of diseases that show abnormal laboratory examinations. The third part is a short synopsis of the pathologic physiology of the body fluids and excreta, and the concluding part takes up methods of collecting and preparing body fluids and tissues for the laboratory. Such an organization is well adapted to the needs of the busy practitioner of medicine but it is doubtful whether the unusually brief treatment of the various subjects will satisfy his needs. It would also appear logical to have the third part, which deals with the pathologic physiology of body fluids and excreta, occupy the introductory chapter. In interpreting laboratory results one must transform laboratory data into a clear concept of the physiologic biochemical and pathologic changes that could explain them. This section, aside from its position in the text is not comprehensive enough to give the physician the necessary fundamental understanding of the laboratory test. The judicious use of diagrams or illustrations would have aided the text considerably. In a book as concise as this, a well selected bibliography would have been advantageous to the reader who desired to go beyond the information given in the text. The data included in the book are for the most part well selected and current. The volume is intended primarily for the physician who desires a concise statement on the interpretation of laboratory work.

Röntgenkymographische Bewegungslehre innerer Organe. Von Dr med habil Pielhart Stumpf Dozent für Röntgenologie an der Universität München Dr med H H Weber Röntgenfacharzt in Bern und Dr med habil G A Weltz Röntgenfacharzt in München Mit Beiträgen von Dr med. W Böhme et al Paper Price 42 marks Pp 516 with 447 Illustrations Leipzig Georg Thieme 1936

This book represents a remarkable series of studies made with a technique which is just coming into common use. As usual with such matters, the idea was put forth early in the history of roentgenology but was not used until recently when apparatus was worked out and perfected. The original idea was to put a metal grid with a series of narrow slits between the patient and the film, and then during the exposure to move either the film or the grid. If, then, as in the case of the heart, there is movement of the walls of the organ such movement will show up as saw-tooth indentations in the shadow on the film. In this way it is possible to analyze minutely the movements of the various parts of an organ. Furthermore, by passing a fine beam of light through the part of the film containing the saw-tooth indentations and on to a photo-electric cell, and then recording the variations in the current with the help of a galvanometer and a mirror which writes on a moving sheet of light-sensitive paper, a curve can be obtained which closely resembles that obtained with a heart lever or with one of Wiggers pressure recording capsules. By putting the films also into a suitable apparatus and moving them in relation to the grid the student can obtain a visual impression of the original motion of the organ studied. The book shows pictures of several pieces of apparatus which have been developed for the making of the films and for their analysis. The grid or the film may be moved up or down or laterally or diagonally and one can not only study the type of movement on the edges of the organ but also get some idea of the changing volume. Careful studies have been made not only of the heart and blood vessels but of disturbance in respiration and in the movements of the diaphragm in diseases such as asthma and tuberculosis. There is a chapter on movements of the esophagus stomach and duodenum, and the urologists are also making use of the new technique. Although any one who looks through this book must be impressed with the tremendous amount of work that has been done and with the possibilities for exact recording of movements in various organs he will be inclined to wonder how much new can be learned which will be of value either to the physiologist or to the clinician. One wonders how often this new technique will give information that cannot be secured in the older and simpler ways. So far as we can see now, it looks as

if it will be most useful clinically in the study of those puzzling cases in which it is hard to distinguish between a tumor of the mediastinum and an aneurysm. The book is well written and beautifully illustrated and it will doubtless be a classic in the literature of roentgenology.

An Index of Treatment. By Various Writers Edited by Robert Hutchison M.D. LL.D. F.R.C.P. Consulting Physician London Hospital Eleventh edition Fabrikoid Price \$12 Pp 1020 with 147 Illustrations Baltimore William Wood & Company 1936

In this day when it is so much the fad to gather together a number of treatises within single covers and call it a book, it would seem almost unpatriotic to question the soundness of the method as exemplified in an American conglomeration of the sort, since the custom is in fullest bloom on our side of the Atlantic. The present book being British, however, one may perhaps point out with impunity that it shares with all other tomes similarly put together the fault of lacking completely in cohesion and readability. Presented in the same format and by the same publishers, this index may be looked on as the companion volume to the equally well known index of differential diagnosis of which French is the editor. Dr Hutchison who presides editorially over the present volume, has as contributors ninety-one men, some writing only one article and some a great many. It is certainly an inclusive work in our crude American jargon offering something for what-is-the-matter-with-you, be it mere symptom, well recognized disease entity, or a complaint of the rarefied nature of erythrocytosis crurum puellarum frigida. Despite this encyclopedic nature, the general practitioner for whom the compilation has been put together must be at a loss nevertheless to understand the many imbalances in space allotment. For example, he will find not quite two pages on the important subject of eczema, yet immediately preceding in the alphabetical arrangement are twenty-two pages on electrotherapeutics. Similarly there are three pages on intubation in diphtheria, which has never yet been learned from a book, but the medical treatment of duodenal ulcer is given only slightly more than one page. The surgical treatment of aneurysm has eight pages, hypnotism a similar number, there are sixteen on foreign bodies in the air passages and esophagus, twenty-five on fractures of the long bones (including much on open operative procedures), and so on. The fact that the book has continued to appear at irregular intervals for nearly thirty years indicates that it must be much relied on by its British medical public, but one wonders whether the eminence of many of the contributors in their special fields and the general excellence of their articles entirely compensate for the facts that with few exceptions each author writes only of his own experiences and that there is not a single bibliographic reference in the entire 1,020 pages.

Über Sternalpunktionen. Von Elsa Segerdehl Med. Lic. Akademisk arhandling som med tillstånd av medicinska fakulteten vid Uppsala Universitet för ernående av medicine doktorsgrad offentlig förvaras Acta medica Scandinavica supplementum LXIV Paper Pp 162 with 16 Illustrations Uppsala Appelbergs Boktryckeriaktiebolag 1935

This is a comprehensive monograph on sternal bone marrow puncture. The first three chapters are devoted to a historical sketch of bone marrow puncture, the structure of bone marrow and the technique of sternal puncture. The author points out that with an increasing volume of bone marrow puncture material the absolute number of cells becomes lowered as the result of the admixture of blood with specific bone marrow cells. She therefore advises working with a small volume and she has selected 0.2 cc. Even with this precaution the absolute number of cells may vary and the values in different punctures in the same individual show decided fluctuations. The following chapters are concerned with a description of the morphology of normal and pathologic sternal punctures. The author discusses the various views concerning cell development but follows the belief that the youngest myeloblasts are the same stem cells of the erythrocytic and granulocytic systems. The point is emphasized that too much stress should not be placed on one bone puncture, as a different picture may be obtained in the same person with multiple punctures. Bone marrow puncture is only a needle investigation of a great organ of heterogeneous composition. Refinements of counting technique also are desirable. The limitations of the various techniques are discussed. The author could not find any essential difference in the bone marrow picture for young men and young women, but in older persons the specific bone marrow elements were lower

in both sexes. In the pathologic conditions involving the erythropoietic tissue two types of anemia are chiefly considered, essential hypochromic and pernicious anemia.

The author's investigations substantiate the results obtained by other authors that in essential hypochromic anemia there is hyperplastic marrow with normal erythrocyte precursors while in pernicious anemia there is hyperplasia with a megaloblastic type of regeneration, which disappears during a remission. By bone marrow puncture the author was able to demonstrate the effectiveness of an injectable antipernicious anemia preparation more quickly than by any other method. With large doses of parenterally injected liver extract a reversal of the bone marrow picture can be seen in twenty-four hours. The use of bone marrow punctures in leukemia is next discussed and the author cites cases in which the procedure has been a distinct diagnostic aid. The author cites cases that clinically presented a characteristic picture of malignant neutropenia whereas bone marrow puncture disclosed the correct diagnosis. Cases of leukemia with prolonged anemic and leukopenic prodromes were correctly diagnosed only by sternal puncture. The final chapter summarizes the value of bone marrow puncture in diagnosis of obscure anemias and leukemia. Arnkin's method is preferred to that of Seyforth because of its simplicity. The author emphasizes, however, that a single cell poor puncture cannot be evaluated as a sign of bone marrow atrophy because of blood mixing with the marrow tissue. A high cell count with pathologic forms is more significant. A familiarity with normal bone marrow puncture smears is most desirable as a prerequisite in interpreting pathologic cases correctly.

The monograph is mainly a consideration of technic and interpretation of bone marrow punctures. The author shows a working knowledge of her subject and her statements are based on carefully evaluated results. The pertinent literature is well handled and the text is well illustrated with black and white photomicrographs. The work should prove of great value to the hematologist and the pathologist.

Theory and Practice of Psychiatry. A Psychiatric Textbook for Neuropsychiatric Specialists and General Practitioners of Medicine. A Reference Handbook for Psychologists, Sociologists, Pastors and Other Professional Readers. By William S. Sadler, M.D., Chief Psychiatrist and Director, The Chicago Institute of Research and Diagnosis. Cloth. Price \$10. Pp. 1,231. St. Louis: C. V. Mosby Company, 1936.

This large tome covers much more material than does the usual textbook in psychiatry. Most textbooks have been confined to a study of the psychoses with an occasional chapter concerning the neuroses and possibly another on mental hygiene, but the present volume is different. It consists of five parts. There is a historical introduction before the first part which is somewhat fragmentary, mentioning in a few paragraphs ancient, medieval and modern psychiatry with reference to Freudian and Adlerian psychology and schools of purely psychologic thought, such as the gestalt school. The present work is the first that incorporates a significant discussion of Adolf Meyer's psychobiology. One question, whether Dr. Meyer would be entirely convinced of the accuracy of this discussion. The author's discussion of this theory as involved in psychiatry goes into a great many different points of view. It discusses mental mechanisms, the unconscious and the subconscious, the significance of dreams, and other attitudes. It includes as do the works of other writers, a discussion of symptomatology, diagnosis and prognosis of mental disease entities and includes a description of methods of examining. The point of view is distinctly eclectic. The terminology of dynamic psychology is used to the extent that Freudian mechanisms are described in a condensed form but beyond that the author does not go.

Sadler's classification of disease entities can scarcely be accepted. It has never been presented before such groups as the Classification Committee of the American Psychiatric Association and there are spots where there are duplications and subclassifications which are of questionable significance to the psychiatrist who is actively engaged in the field.

The second part of the volume dealing with personality problems is a conglomeration of material taken from elementary books on child training rather superficial attitudes on the development of personality and also short chapters on family relationships and adult personality which after all are significant to the psychopathologist.

The third part of the volume is composed of a discussion of the neuroses which is interesting because of the fact that

for the first time the subject is extensively covered in a text book. However, here again there are duplications, and the author's attempt to combine all neuroses into either psychasthenic states, neurasthenic states or hysterias is open to grave question. There is insufficient discussion of the dynamics of these important subjects, but the author should be commended on the fact that this is the first textbook on psychiatry to go into the subject with any degree of completeness.

The fourth part is devoted to the psychoses. Here there is little difference between Sadler's presentation and that of the conventional psychiatric textbook.

The last part is devoted to psychotherapeutics. There are about 250 pages devoted to this important matter. Suggestion, hypnosis, rest and relaxation, play and recreation, and many other topics are discussed in brief and, while here again there is no tremendous depth to the discussion, the interested student will find much stimulating material. There is an excellent glossary at the end of the volume, although one must differ somewhat with some of Sadler's definitions. At the end of each chapter there is a bibliography largely consisting of elementary texts on the subject of the chapter rather than of specialized scientific articles.

The most severe criticism which can be laid against the volume is the fact that, while there is so much material which is included which is interrelated, on the other hand there is a great deal of duplication and considerable overemphasis on classification. Certainly the well trained psychiatrist is going to differ in many respects with Sadler's point of view and many probably will reject the book entirely, particularly because of its moral and religious undercurrent. For elementary students it may give a leading idea of psychiatry.

Les hépatonéphrites algues. Etude clinique, anatomique et expérimentale. Par Jean Vague, assistant à la Faculté de médecine de Marseille. Travail de la clinique médicale du Professeur D. Olmer et du laboratoire de médecine expérimentale et d'anatomie pathologique du Professeur L. Cornil. Paper. Price 70 francs. Pp. 640 with 42 illustrations. Paris: Masson & Cie, 1935.

The author has attempted to correlate the clinical, anatomic and experimental features of hepatic and renal disease accompanying severe toxemias and infections under the caption "acute hepatonephritis." The book contains evidence and arguments on which the author bases his thesis, the subject being presented in nine chapters dealing with the historical aspects, clinical features, experimental phases and pathologic observations. Much emphasis is placed on etiology and pathogenesis. The bibliography is extensive, although mostly from the French literature. The typography is excellent and the photomicrographs are good. Hepatonephritis is regarded as a syndrome due to elective and systematic injury simultaneously to the liver and the kidneys, the term having been applied originally by Richiardi in 1890. The etiologic agents are varied, including such poisons as carbon tetrachloride, cinchophen, mercury, uranium, phosphorus, diphtheria toxin, and mushroom poison. Infectious agents, for example the spirochetes of infectious jaundice, the virus of yellow fever and generalized bacterial infection by both aerobic and anaerobic micro-organisms are frequent causes. The symptomatology is considered in detail under the syndromes "icteric," "vasculosanguine," "toxic" and "biologic." The clinical signs and symptoms for these types are presented in detail and are correlated with the chemical changes of the blood and urine. The chapter dealing with etiologic factors contains many case records supplying clinical details and chemical observations supporting the principal thesis of the author. Attempts to simulate these conditions experimentally are described in the chapter on experimental studies. Various kinds of animals were tested with such poisons as apoll mushroom poison, uranium, cantharidin and the toxins of the diphtheria and perfringens bacilli, and the toxic syndrome simulated closely that observed in man. The pathologic changes also were similar to those found in man. The section on pathologic anatomy is well presented, illustrated by numerous photomicrographs. An attempt is first made to summarize present conceptions regarding inflammation of the liver and kidneys. Necropsy material is then described histopathologically and an attempt made to analyze the results. Finally, an anatomic classification of acute hepatonephritis is suggested. The concluding chapter contains a few suggestions with regard to treatment with emphasis on the importance of proper feeding with carbohydrate diuresis, alkalization and

the intravenous use of chlorides. The book is a whole represents a vast amount of labor in gathering together the clinical, experimental and pathologic facts relating to severe acute injury to the liver and kidneys. Clinicians interested particularly in metabolic disturbances of the liver and kidneys will find the book stimulating. Pathologists will be interested in the French view with respect to acute hepatic and renal disease.

Die Zuckerkrankheit. Von Prof. Dr. Wilhelm Falta. Paper. Price 15 marks. Pp. 322. Berlin & Vienna: Urban & Schwarzenberg, 1936.

This is a storehouse of the author's experience and of the literature on diabetes and is written in the best German style. It contains more than 1,100 references and a liberal share of these are articles that have been published during 1934, 1935 and 1936. Any student of diabetes will wish to possess the book. Professor Falta has been in the thick of diabetic work during the thirty years of his active medical career in Vienna; he has been a prominent clinician. These pages, therefore, allow one to see in perspective not only the contributions of Falta and his many associates to diabetes but the places these occupy in the unfolding of diabetic knowledge during the last generation. The text is written in a simple and attractive manner and makes easy reading for English-speaking doctors, perhaps because of the author's sojourn years ago in the United States. The book contains facts and less of theory than certain of Falta's earlier writings. Professor Falta has kept in close touch with the work of American investigators and credit is given liberally to what has been done here. There are few pages in the book that do not contain some phrase, sentence or paragraph to be noted for future use. What one does miss comes from an evident lack of intimate association of the medical diabetic clinic with the surgical and obstetric diabetic clinics such as is in force in various parts of the United States. This has led the author to less optimistic conclusions about the desirability of aggressive surgery for gangrene and early delivery in the course of pregnancy than would otherwise be the case. The same holds true regarding the situation of diabetic children. One regrets that the author has not had an opportunity to see the larger camps for diabetic children, which are in this country such a feature in treatment. One's ideas regarding diabetes alter materially when privileged to see seventy diabetic children in camps during the course of one day, many of them taking insulin protamine. Such a visit awakens a hopeful attitude which it is hard to overestimate.

The Patient and the Weather. Volume 1. Part 2. Autonomic Integration. By William F. Petersen, M.D. With the assistance of Margaret E. Milliken, S.M. Cloth. Price \$0. Pp. 781 with 366 illustrations. Ann Arbor: Edwards Brothers, Inc., 1936.

The author of this volume is developing from many angles what is a most unusual work. First of all the volumes are published beginning with the last and working forward. The present book is the second part of the first volume, leaving the first part of the first volume the only part now to be issued. There is a tremendous amount of information in this book, which is devoted to the influence of the weather on autonomic integration. Since the author now discusses in much detail comprehensive information about cyclonic circulation, temperature, humidity and other meteorological material, the real object of this ponderous research is beginning to be apparent. A brief summary of the book is almost impossible for all sorts of relationships, physical facts and characterologic phenomena are pointed out, discussed and illustrated. To pick out a few chapters, one might point out that there is a discussion of the urine with relation to volume, acidity, phosphorus, effective meteorologic rhythm and other subjects. There are chapters on headaches, colds, gastro-intestinal disturbances, moods and psychologic implications, growth reaction of children, studies in blood changes, and a large chapter is devoted to season, climate and climatic cycles as regards tranquillity and variability physiologic and chemical alterations, morbidity and death. The book is summarized in a chapter entitled "The Human Organism as a Cosmic Resonator." This volume like the others is profusely illustrated with meteorologic graphs, chemical diagrams, maps, and photographs of subjects and of clouds. There are innumerable tables, many thorough case histories, and a detailed bibliography after each chapter. Some of the graphs are extremely complicated having a multiplicity of changes in the many factors compared. All in all this monograph is a thoroughgoing piece of work which has some

tendency to bear out the author's various predilections about the relationship of the weather to bodily functions. The basic idea would seem to be that there are vascular and autonomic complexes which correlate with either temporary or long-time changes in the weather. It is difficult to point out any particular class of readers to whom the book will be most useful. It is too ponderous for the average physician, yet a physician or research man will want to know what Petersen has to say about the relation of the weather to his own particular field of interest.

Lehrbuch der Inneren Medizin. Von H. Assmann et al. Bände I und II. Third edition. Paper. Price 48 marks per set. Pp. 934 with 171 illustrations. 846 with 153 illustrations. Berlin: Julius Springer, 1936.

This appears just two years after the second edition. Every effort has been made to bring the book to date. A new chapter has been added on pathologic heredity of internal diseases written by Professor Siebeck. The chapter on general therapy by Professor Stachelin has been completely rewritten and the chapters on the diseases of the respiratory tract, metabolism, muscles, bones and joints have been thoroughly revised. The book is well illustrated and the roentgenograms, especially in the chapter on respiratory diseases, written by Assmann, himself a foremost radiologist, deserve favorable mention. There is an exhaustive subject index, an author's index is missing. The textbook in its present form fulfils its purpose as a valuable source of information for the student and the practitioner. The specialist probably will find his respective field not covered thoroughly enough and the literature especially American, not completely considered. As a whole, however, the difficult task of presenting a modern cross section of the present state of internal medicine has been met successfully.

Diseases of the Nose, Throat and Ear for Practitioners and Students. Edited by A. Logan Turner, M.D., LL.D., F.R.C.S.E., Consulting Surgeon, Ear and Throat Department, Royal Infirmary, Edinburgh. With the collaboration of J. S. Fraser, M.B., F.R.C.S.E., Surgeon, Ear and Throat Department, Royal Infirmary, Edinburgh and others. Fourth edition. Cloth. Price \$6. Pp. 473 with 264 illustrations. Baltimore: William Wood & Company, 1936.

This deservedly popular textbook continues to remain among the best of its type in our language. The text is concise but lacks little in information necessary for the student, general practitioner or even the specialist desirous of authoritative opinion. The illustrations on the anatomy of the ear, nose and throat as well as those on clinical pathology cannot be too highly praised. They have been carefully selected and their clarity leaves nothing to be desired.

Archiv und Atlas der normalen und pathologischen Anatomie in typischen Röntgenbildern. Röntgenatlas der Staublungenkrankungen der Ruhrbezugsleute. Von Dr. G. Schulte, Leiter der Röntgenabteilung am Knappschafts Krankenhaus Recklinghausen. Unter Mitarbeit von Dr. K. Husten, Prosektor der Ruhr Knappschaft am Knappschafts Krankenhaus Essen-Steele. Fortschritte auf dem Gebiete der Röntgenstrahlen. Ergänzungsband L herausgegeben von Prof. Grashey. Paper. Price 24 marks. Pp. 141 with 153 illustrations. Leipzig: Georg Thieme, 1936.

During the last five years this country has seen a frenzy of litigation centering about claims for silicosis among industrial workers. Often in these trials an unpraiseworthy medical spectacle has arisen because of the testimony of well meaning physicians lacking both experience and training to qualify them for technical testimony concerning silicosis and particularly the roentgenologic aspects of silicosis. Apparently a somewhat similar situation has arisen in Germany, for the purpose of this German roentgen atlas is better to acquaint the general practitioner with the x-ray characteristics of silicosis, silicotuberculosis and tuberculosilicosis. After a cursory discussion of the pathology of silicosis, its various degrees of severity and its status as an occupational disease, the greater part of this book is devoted to excellent reproductions in reduced size of roentgenograms. Part I presents twenty-five reduced size illustrations with two supplementary inserts of the actual size of the original film. The pictures in part I are designed to portray the different stages of silicosis alone and of silicosis associated with tuberculosis. Materials from twenty-six cases appear in part II, showing the evolution and progress of the disease, with emphasis on serial manifestations rather than on the finer details that are emphasized in part I. Two or three plates are shown for each case. An appendix of five plates is added to bring out the differential diagnosis between silicosis and tuberculosis. The reproduction of roentgenograms for publication purposes is nearly always unsatisfactory. This German publica-

tion, however, presents with great fidelity the appearance of nonstereopticon x-ray films. It is obvious that no reproduction can approach the original in clarity and refinement of detail, but here the printer's workmanship is of high order and constitutes a most commendable feature of this publication

Diseases of the Respiratory Tract. Eighth Annual Graduate Fortnight of the New York Academy of Medicine. By 21 contributors. Cloth Price \$5.50. Pp. 418 with 50 illustrations. Philadelphia & London: W. B. Saunders Company, 1936.

This comprises a series of lectures delivered before the graduate fortnight of the New York Academy of Medicine by specialists in the various phases of medical and surgical dealing with diseases of the respiratory tract. Manifestly it is impossible to give an adequate review of each lecture. The subject matter is well covered and the book can be recommended both to the general practitioner and to the specialist.

MEDICOLEGAL ABSTRACTS

Optometry Practice Acts Replacement of Broken Lens as Constituting the Practice of Optometry.—The replacement of an ophthalmic lens, said the Supreme Court of Appeals of West Virginia, by an optical mechanic by means of taking the measurements from a broken lens and manufacturing a new lens from such measurements does not constitute the practice of optometry in West Virginia. It constitutes the replacement of the lens by doing the "merely mechanical work" by an optical mechanic, as authorized by the optometry practice act.—*State v McGrail (W Va)*, 183 S E 686

Workmen's Compensation Acts Silicosis and "Wage Loss"—Marsz, a man 59 years of age who had been in the employ of the Schaefer Monument Company for twenty-six years, was discharged when a physical examination, required of all employees of the company by its new insurance carrier, showed that he had silicosis. Marsz claimed at that time, however, to the examining physician that he was all right and could continue to do his work. Subsequently he instituted proceedings under the Wisconsin workmen's compensation act before the industrial commission. An examiner for the commission found that Marsz was suffering from silicosis in an advanced stage, caused by the exposure in his employment, and that since as a result thereof he was incapable of more than slight physical exertion and could be employed only in occupations which involve so-called light work he was 50 per cent disabled. The industrial commission confirmed those findings and awarded compensation accordingly. From a judgment of the circuit court for Dane county affirming the award the employer and his insurance carrier appealed to the Supreme Court of Wisconsin.

In general, the Wisconsin workmen's compensation act provides for compensation for such disability whether resulting from accidental injury or from occupational disease arising out of and in the course of employment, as results in a wage loss. The appellants seem to have contended that Marsz had suffered no wage loss. Wage answered the Supreme Court of Wisconsin is dependent on two factors. Time and rate of compensation. In *Zurich General Accident and Liability Ins Co v Industrial Commission* 203 Wis 135 233 N W 772 this court held that a worker who was transferred from a place of exposure to outside work at a diminished wage suffered a wage loss that is his rate of compensation per unit of time was diminished. The real source of difficulty the Supreme Court continued in silicosis cases is that many men suffering from the ailment in some of the various stages are able to and do continue to work and receive full compensation therefor long after they have sustained what has been referred to as a medical but what might be more properly referred to as a pathologic disability and therefore as a matter of fact sustain no wage loss. It is because the legislature has so far seen fit to withhold compensation for physical impairment which does not

immediately result in the physical incapacity of the claimant to work that the difficulty in these cases springs. There is a feeling that a person who has sustained loss of physical vigor and had his system invaded by foreign substances which may and often do result in impairing his ability to work and not infrequently in death, should have compensation. If, however, the legislature had intended the term "disability" to embrace so called medical or pathologic disability as distinguished from actual physical incapacity to work, it would undoubtedly have said so.

This court, continued the Supreme Court has previously held that the injury or wage loss to be compensable must be sustained at a time when the relation of employer and employee existed. An amendment to the workmen's compensation act adopted thereafter (Laws, 1933, c. 314 sec 27) provides that the time of injury or the occurrence of disability shall be deemed to be the last day of work for the last employer whose employment caused the disability. This obviously refers the time of injury or disability back to a point in time when the employer and employee relationship existed. Even if a plant shuts down and an employee is discharged and is not thereafter employed if he is thereafter disabled the time when his disability occurs is referred to the last day of employment which caused his disability. In the case at bar when it is considered that admittedly Marsz is suffering from silicosis that as a result of it he is incapable of more than light physical exertion, that by reason of his physical incapacity he can be employed only in occupations which involve so-called light work, this court cannot say that there is no evidence to sustain the finding of the industrial commission that Marsz has sustained a wage loss, which, measured by the rate of compensation he had theretofore received, amounts to 50 per cent. The award in favor of the worker accordingly was affirmed.—*Schaefer & Co v Industrial Commission (Wis)* 265 N W 390

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them. Titles marked with an asterisk (*) are abstracted below.

Thymoma and Thymic Hyperplasia in Myasthenia Gravis.—Norris is of the opinion that pathologic changes may be found in the thymus in cases of myasthenia gravis in direct ratio to the care with which they are sought. With the addition of the four cases described here and the six reported elsewhere since 1917 the incidence of thymic lesions remains at 50 per cent. This figure probably expresses the frequency of grossly recognizable lesions of the thymus. It seems possible, however, that thymic lesions which have produced little or no macroscopic alteration of the suprapericardial tissue may have been overlooked in some of the reported cases. The author lists in chronological order the cases of myasthenia gravis in which the necropsy disclosed thymic lesions. In discussing the material the author points out that of the thirty-five cases tabulated eighteen were classified by the various authors as representing instances of an enlarged or persistent thymus and seventeen cases were classified as tumors of the thymus. These reported cases therefore, are divided into two almost equal groups. A casual survey of the descriptive data indicates that the line of separation is not sharp and that the bases for distinctive classification are uncertain. In some of the cases listed as enlarged thymus the thymic mass was as large as or larger than certain of those designated as tumors. The difficulties encountered in differentiating between a benign thymoma and an enlarged thymus in which there is an extensive epithelial hyperplasia is well illustrated by two of the cases of the group of four

described in detail. The author decided to designate the pathologic conditions that have been regarded as benign tumors of the thymus as conditions of extreme epithelial hyperplasia and the pathologic conditions that have been regarded as instances of enlargement or persistence of the thymus as conditions of moderate epithelial hyperplasia.

Endocrine Factor in Etiology of Mammary Tumors

—According to Taylor, any attempt to define the stage to which clinical and experimental work has carried the theory of an endocrine cause for breast cancer is difficult and is certain to receive little approval. He nevertheless offers the following points as perhaps the most important. 1 The ovarian hormone is essential for the development and preservation of the epithelium of the mammary gland. Without it there is no tissue on which any carcinogenic agent may act. This is the most obvious reason why cancer of the breast does not develop in early castrates or in untreated male mice. 2 The development of breast cancer in mice after the injection of large quantities of estrogenic substance may be brought about in several ways: (a) by a direct carcinogenic action comparable with that of various tar derivatives, (b) by increasing the normal physiologic impulse to proliferation until it produces atypical structures, (c) by the production of abnormal activities of the cells the secretions of which provide the carcinogenic factor. 3 Tumors of the human mammary gland are also dependent on the ovary at least to the extent that the normal tissue from which the tumors must arise are provided by the ovarian hormone. 4 An existent ovarian function is apparently essential for the common types of chronic mastitis and fibro-adenoma, the development of which is practically limited to the years of mature sexual life. This is not true of carcinoma, which may appear long after the menopause. 5 With the neoplastic disease once established, a marked response to variations in glandular function, such as those incident to pregnancy and the menopause, is noted in chronic mastitis and fibro-adenoma. A moderate reaction to these changes is observable in some cases of carcinoma. 6 Some evidence of a glandular dysfunction can be found in certain cases of chronic mastitis, but hormone states comparable to those necessary to produce mammary carcinoma in mice by the injection of estrogenic substance are unknown in women. 7 There is no clinical evidence yet of any specific endocrine dysfunction as the cause of human breast cancer.

Alkalinized Milk Tablets in Peptic Ulcer.—Wosika points out that in a previous paper he and his collaborator Emery evaluated the effect of the routine Sippy treatment on the control of acidity in forty-six cases of duodenal ulcer. It was found that symptoms were abolished and that the free acidity was adequately controlled in slightly more than half. A

second report compared the use of a liquid mixture of powdered whole milk, in addition to an alkali powder, with the routine Sippy procedure and demonstrated that the former was the more effective as a neutralizing agent. The purpose of the present study is to determine the value of tablets composed of powdered whole milk and varying amounts of alkalis on the neutralization of the gastric acidity in patients with peptic ulcer. For this study twenty-six patients with peptic ulcer were selected from the medical clinic of Northwestern University. Roentgenologic evidence for ulcer was positive in all save two cases and the clinical history of both of these exceptions was too typical to doubt. All the patients were men between the ages of 26 and 66 years. The average age was 44 years. Ulcer symptoms had been present from one to twenty years, with an average of nine years. Three of the group had gastric ulcers and because they had relatively high acid values as determined by a histamine gastric analysis they were included in the series. The patients reported to the clinic about once a week in the morning and all meals (the usual foods allowed on the fourth week Sippy regimen) were served at Passavant Memorial Hospital at 8 a. m., 1 p. m. and 6 p. m. Between meals they were given tablets or milk and cream. The author found that tablets composed of powdered whole milk (12.5 Gm.), sodium bicarbonate (0.6 Gm.) and calcium carbonate (2 Gm.) are slightly more effective than the routine Sippy procedure as regards the neutralization of the gastric acidity.

Pectin-Agar Preparation for Treatment of Diarrhea of Infants—Winters and Tompkins show that objections are raised to scraped raw apple as a treatment for diarrhea. A substitute is offered, made with pectin agar-agar and a dextrin-maltose preparation. Observations and data are recorded on twenty-four patients treated with this substitute and on eighteen patients treated with scraped raw apple. Data are offered to show that the group treated with the substitute responded better than the group fed scraped raw apple.

Abdominal Syndrome of Rheumatic Disease—Wolfe and Brim call attention to a group of children in whom recurrent abdominal cramps lasted from six months to several years and apparently were the only subjective manifestation of an active phase of rheumatic disease. They present cases illustrating the importance of recognizing the existence of an abdominal syndrome of rheumatic disease. They think that excepting indiscretion of diet active childhood rheumatism is probably the most important cause for such abdominal symptoms. Provided the attacks of cramps are transitory and apparently inconsequential. Other manifestations of the active phase of rheumatic disease are frequently associated with it such as pallor, weight fixation in spite of a properly balanced diet, irritability without any apparent cause, twitchings and tics often looked on as habit spasms because of their chronicity, aches and pains in various joints and muscles often attributed to rapid growth and enuresis after the control of the bladder has been established. In spite of the fact that several of these manifestations are invariably seen in any case the condition

is frequently overlooked, and an active rheumatic state is often unrecognized until organic heart disease is accidentally discovered during the course of a physical examination. The authors are convinced that the greatest degree of cardiac change occurs during the unrecognized active phase of the disease.

Chronic Progressive Postoperative Gangrene of the Abdominal Wall—Willard reports the case of a woman aged 57, who underwent an operation for acute appendicitis. The appendix showed beginning gangrene. The woman was

discharged from the hospital on the nineteenth day following operation. Soon after, however, the wound began to break down rapidly, and, in spite of the fact that the drainage from the depths of the wound gradually ceased there developed a progressive spreading gangrenous ulceration of the skin and subcutaneous tissues. The patient was given a blood transfusion and antistreptococcus serum without apparent benefit. The first bacteriologic cultures that were taken on her readmittance to the hospital showed an enormous number of hemolytic streptococci with an occasional colony of staphylococci and *B. coli*. From the necrotic tissue a hemolytic staphylococcus was obtained. Cultures taken from a piece of tissue excised from the red area adjacent to the normal skin gave, by the anaerobic technique, a growth of nonhemolytic anaerobic streptococcus in pure culture. After two generations, this nonhemolytic anaerobic streptococcus showed slight aerobic growth on Loeffler's blood serum. This corresponds culturally to the organisms which Meloney had found in similar cases. He has designated this as "micro aerophilic." Following radical excision, the wound was dressed daily with gauze saturated with a suspension of zinc peroxide in sterile water, which was covered with petrolatum gauze to prevent drying. Later skin grafting was done. The author says that Meloney described several different types of superficial infectious gangrene. Examples of the acute types are gas gangrene and hemolytic streptococcus gangrene. Neither produces marked local pain or sensitiveness, but both produce extreme prostration and result in a high mortality. The case described in this report represents one of the more chronic forms of infectious gangrene. In the conclusion the author points out that this condition represents a rather rare instance of chronic infectious, superficial progressive gangrene which belongs to a definite clinical group and which should be recognized clinically. It is differentiated clinically from other types of superficial gangrene by its slow and relentless progression, its severe local symptoms and the absence of severe systemic symptoms. It is characterized bacteriologically by the fact that it is produced by two organisms neither of which alone may be virulent but which in combination produce a virulent infection. It is important that the nature of this infection be recognized early and that wide and radical excision be employed promptly.

Serum Phosphatase in Fracture Repair—Mitchell studied a series of seventy-five unselected major fractures in order to determine the possible clinical significance and the relationship between the healing of fractures and the activity of the enzyme phosphatase of the serum. Serial determinations of serum phosphorus and phosphatase were made the day following fracture and thereafter at weekly intervals for the following three weeks. In a few cases the studies were followed until union was complete. With the knowledge that diet especially a high carbohydrate diet, could produce variation in the serum phosphatase level, it was thought advisable to keep these patients on a standard diet. However, it was found to be very difficult to keep this number of patients on a weighed diet over the length of time necessary and accordingly a uniform diet was planned and given in all fracture cases under study. The Bodansky method of phosphatase determination has been used throughout in this series. According to Bodansky the average normal adult serum phosphatase reading is 26 units, with levels ranging from 1.5 to 4. In serial determinations on normal individuals taken at weekly intervals an average fluctuation of about one unit has been found. Accordingly in computing whether there has been an increase or decrease in the serial determinations in this series, allowance has been made for this error. On the basis of his studies the author reaches the following conclusions: 1. There is not a consistent rise in the serum phosphatase level in the course of fracture healing, although in many cases there is a slight increase, while in a smaller group there is a decrease. 2. The increased serum phosphatase activity following fractures appears to be secondary to the increased activity at the fracture site and not vice versa. 3. The serum phosphatase level following fracture is not an index of the healing or rate of healing of the fracture. 4. No significant change in the blood phosphorus level following fracture was noted.

Chronic Pulmonary Infection Due to Friedländer Bacillus—Collins points out that in a previous publication his associates and he described the clinical and roentgenologic features of three cases of pneumonia with recovery and expressed the belief that the organism responsible for the production of the pulmonary lesion was the Friedländer bacillus (*Bacillus mucosus-capsulatus*). The author's purpose in the present paper is to present follow-up data on these three original cases and to record observations on a fourth nonfatal case in which they succeeded in isolating the Friedländer bacillus in a culture of the blood during the height of the pneumonia. One of the three patients on whom follow-up data are presented was still living more than seven and one-half years after the attack of pneumonia. One patient died of an apparently unrelated infection two years after the attack of pneumonia. The third patient was lost from view. The fourth patient, in whom the Friedländer bacillus was isolated from both the sputum and the blood during the acute stage of the pneumonia, is now doing manual labor, more than two and one-half years after the attack of pneumonia. At the site of the original pneumonic lesion there are still marked clinical and roentgenologic signs. The end result of pneumonia due to the Friedländer bacillus, both clinically and roentgenologically, almost completely simulates chronic pulmonary tuberculosis in that it produces cavitation, displacement of the trachea, elevation of the domes of the diaphragm and elevation of the hili of the lungs.

Raynaud's Disease in Association with Sclerodactylia—Prinzmetal states that sclerodactylia and scleroderma are often associated with Raynaud's disease. Most frequently the changes in the skin occur after the vasospastic syndrome has been present for some time. Sclerodactylia occasionally occurs without pathologic arterial spasm and in some cases may precede the attacks of local asphyxia of the fingers. Occasionally the changes in the skin and the vasospastic attacks in the fingers begin simultaneously. The author demonstrates that Raynaud's syndrome in association with sclerodactylia has a more severe clinical course and presents a more difficult therapeutic problem than uncomplicated Raynaud's disease, and the experimental vascular reactions differ in the two conditions. Important causal factors in sclerodactylia are the tight, inelastic skin and subcutaneous tissue of the fingers which constrict the blood vessels and diminish the blood flow. In sclerodactylia the areas of greatest circulatory insufficiency coincide with the areas of greatest change in the skin. Determinations of the temperature of the skin verify this contention. The atrophy of the terminal phalanx in sclerodactylia is probably due to pressure of the tight skin. Whereas sympathectomy raises the temperature of the normal skin and the temperature of the skin of patients with uncomplicated Raynaud's syndrome, little or no rise in temperature takes place if severe sclerodactylia is present, and no clinical improvement follows. It was demonstrated in one

case that, if the tight skin of the finger tip is relaxed, slight but definite improvement in circulation, as determined by the color and temperature of the skin, takes place. If a binding of about the same degree of tightness as that present in sclerodactylia is placed on a normal finger, the abnormal vascular reactions found in sclerodactylia may be duplicated. Vasodilator impulses induced by the Landis heat test for arterial occlusion cause little or no increase in the temperature of the skin in sclerodactylia. Similarly, if a normal finger is bound, little or no rise in temperature takes place. A simple test for arterial occlusion may be performed by the injection of histamine into the terminal phalanx of the finger or toe to be tested. If no organic occlusion is present, the temperature of the skin rises in a short time. In cases of severe sclerodactylia, no rise in temperature takes place after the injection of histamine. If the normal finger is bound, similar results are obtained. The use of intermittent suction, recommended by Herrmann and Landis, may cause an increase in circulation in cases of sclerodactylia, as determined by the temperature and color of the skin, though sympathectomy has failed to produce improvement. It is suggested that the mechanism of improvement is the relaxation of the tight skin. This seems to be the only method available at present which may prove beneficial.

Short Wave Radiation and Blood—On the basis of an investigation of the action of short waves on the constituents of the blood Kobak arrives at the following conclusions: 1. Short wave therapy apparently influences the various constituents of the blood. 2. Minimal dosage of short wave radiation tends to raise the refractometric index, increase the viscosity, raise and lower the blood sugar and increase the sedimentation rate. 3. The changes produced are significant of the internal influence only of short waves and require more detailed correlation on actual clinical material. 4. The applicability of the experimental data to therapy is clearly indicated by their biophysical and biochemical character: the ultrashort regions having a more selective action and a more prolonged heating effect than is found in the longer regions of short wave diathermy.

Chronic Cervicitis—Hoffmann says that, in any treatment for chronic cervicitis with erosion, eversion or laceration, one must bear in mind the histopathology of the condition, that is, the malarrangement of the columnar and squamous epithelium. Whatever line of treatment is adopted, success will not be reached until the pathologic condition is corrected and the underlying and superficial tissues are restored to their normal arrangements and cell layers. Among the plans of treatment are (1) the various chemical applications with or without tamponage, (2) electrical cauterizations, (3) coagulations, (4) radium, (5) surgical and, last but not least, the Crossen conization with the cutting electrode. The author evaluates these different methods and states that at his hospital conization with the Crossen loop has been done with good success. The technic is that used in the Hyams loop but has the distinct advantage over the Hyams loop of accomplishing in one revolution what would take many revolutions for the Hyams loop. The operation with the Crossen loop requires less than one minute and gives a cleanly coned out operative field. It is very unusual for any free bleeding to occur and rarely, if ever, are sutures required. If the conization is properly done and the current is not too hot, little scar tissue is encountered. The author dilates the cervix to about twice its size before conization. He feels that in this way the infected tissue is packed together, the extra edema is pushed out of the tissue and there is not the danger of taking out more than the desired amount of normal tissue at the base of the infected tissue. Other advantages of the conization method besides the assurance of getting the diseased tissue and the reduced amount of cicatricial tissue postoperatively are that it is an ideal method of removing tissue for biopsy, the hospitalization is from thirty-six to seventy-two hours, and there is little loss of blood and no shock to the patient. The author observed more than 200 of these cases all the way from operation through the various stages of healing. Ordinarily the slough has completely gone in from seven to ten days, leaving a clean nonirritated cervix. The cervix at the end of three weeks presents the clean regular appearance of the nulliparous cervix.

Mortality in Tuberculin-Positive Infants—Brailey reports that 170 children of whom seventy-two were white and ninety-eight colored found to be infected with tuberculosis before reaching 2 years of age were kept under observation for periods ranging from one to five years. They can be divided into sixty-seven who showed parenchymal involvement of the

lungs at initial roentgenoscopy and 103 who showed no definite parenchymal lesion when first examined. Twenty-two roughly one third of those with a pulmonary lesion when the infection was discovered, were ill and presented signs of disease such that a diagnosis could usually have been made by ordinary clinical means. The remaining patients gave no indication of their infection, and a diagnosis could not have been made without the tuberculin reaction and the use of roentgen examination. By calculation, following actuarial procedures, the total five-year mortality for white children was found to be 13 per cent and for the colored children 31 per cent. Approximately 70 per cent of the deaths that occurred in five years of observation fell within the first year, mostly within the first six months following the discovery of the infection. This refers to deaths from all causes, but, with few exceptions tuberculosis was the immediate cause of death. Of those admitted with involvement of the lung parenchyma, 31 per cent were dead within the first year of observation, no difference being observed between the two races in case fatality. Among those whose initial chest plates showed no parenchymal involvement, mortality during the first year subsequent to the discovery of infection was 68 per cent. No deaths occurred among the forty-nine white children of this group, but there were seven deaths among fifty-four colored children. In the entire group of colored children observed, mortality has been more than twice that observed in white children. When the pulmonary lesion has developed sufficiently to be readily demonstrable by roentgen ray the fatality is about the same in white as in colored children. However, lesions of this extent are much more frequent in the colored than in the white, and this appears to account for the fact that the gross mortality in the colored is so much higher. In both white and colored children, mortality has been more than twice as high in those known to be infected during the first six months of life as in those whose infection was discovered between the ages of 6 months and 2 years. In about 78 per cent of the white and 64 per cent of the colored children of this study there was intrafamilial contact with a proved sputum positive case. The children of each race with known exposure showed a slightly higher mortality than children not known to have been exposed. The difference in mortality is not statistically significant and a detailed study of a larger series must be made to determine the bearing which continued exposure may have on severity of lesion.

Cutaneous Reactions in Asthmatic Patients—Stevens and Jordani prepared from broth cultures the nucleoproteins used for intracutaneous testing. All the patients studied had asthma. Some were sensitive and others nonsensitive to the common allergens. Tests were first done with the nucleoproteins of the hemolytic streptococcus, *Streptococcus viridans*, *Micrococcus catarrhalis*, the influenza bacillus and *Staphylococcus aureus*. Subsequently some of the patients were tested only with the proteins with which positive reactions had been obtained previously. All the nucleoproteins elicited both immediate and delayed reactions. The immediate reactions may have been due to traces of carbohydrates. This possibility is mentioned because immediate reactions have been evoked by intracutaneous injections of the specific carbohydrates of pneumococci and staphylococci in patients infected with these bacteria. The immediate and delayed reactions to the hemolytic streptococcus, the influenza bacillus and *Streptococcus viridans* were usually transient, although in a few instances delayed reactions continued positive for several months. The immediate reactions to staphylococcus and the delayed reactions to *Micrococcus catarrhalis* were usually of the persistent type. The persistence of these two reactions accounts in part for the high percentage of immediate reactions to the staphylococcus and of delayed reactions to *Micrococcus catarrhalis* when patients are tested consecutively with a number of bacteria among which these two kinds are included. The observation that both immediate and delayed reactions seldom occur at one site of inoculation with a nucleoprotein has been confirmed in the present study. Whereas sixty-three immediate reactions and fifty-three delayed reactions occurred independently of one another, in only six instances were wheals followed by delayed, tuberculin-like reactions. This observation may now be extended with the statement that usually, when an immediate reaction is obtained with a bacterial nucleoprotein, in later tests the patient tends to react in the same manner. Immediate reactions are followed by immediate reactions on subsequent retesting and delayed by delayed reactions, the patient may, however, give an immediate response to one bacterium and a delayed reaction to another synchronously injected. Most reactions have varied in intensity in the course of time. A definite tendency exists on the part of the patient to react habitually to a bacterial nucleoprotein as he has reacted in the past. Attention should be directed to the parallelism between these recurrent reactions of similar type and acute exacerbations occurring in the course of certain chronic diseases. Two examples may be given. In rheumatic fever, pharyngeal reinfection with hemolytic streptococci is followed commonly by recurrence of the rheumatic syndrome. In asthma caused by infection, upper respiratory infections are usually followed by a recurrence of the asthmatic symptoms.

Tuberculous Infection in Childhood—This study was undertaken by Johnson in an attempt to evaluate some of the factors supposed to influence the development of tuberculous infection in children. The group in question comprised 375 children under 16 years of age who were examined at the Health Department Tuberculosis Dispensary in Springfield. Two hundred and eighteen children gave a definite history of contact with a known case of pulmonary tuberculosis, 157 non-contacts were presented for examination because of malnutrition recurrent respiratory infections or vague apprehension on the part of the parent. The examination of each child included a record of the age, sex height weight, temperature, cutaneous tuberculin reaction after forty-eight hours, roentgen examination of the chest, source of contact, period of exposure and an appraisal of domestic hygiene as a result of personal investigation of the home. On the basis of these studies the author reaches the conclusion that close and persistent association with a case of pulmonary tuberculosis especially one with a positive sputum, appears to be the most important predisposing factor in the development of tuberculous infection in children. It has not been possible to demonstrate that the age sex or nutrition of the child the source of contagion, or the sanitary conditions in the home play an important part in conditioning tuberculous infection in the child.

Roentgen Treatment of Hay Fever—Hatchette used roentgen treatment in sixteen cases of hay fever employing 100 kilovolts 3 milliamperes 2 mm of aluminum filtration and a field of 10 by 10 cm. Irradiation was given over the region of the nose the rays being directed slightly caudad in an effort to avoid direct irradiation of the pituitary. The eyes of all patients were protected by lead foil as soon as the first symptoms of improvement here were noted and no patient received more than three irradiations without protection over the orbits.

No other form of treatment was used by any patient during the course of irradiation. Two of the patients were suffering from asthma during the course of treatment and failed to respond to the roentgen rays. One patient failed to return after the second treatment and no results were obtained. One patient failed to show any response from a light year round hay fever but was apparently completely relieved from her 'autumnal' type. The remaining twelve patients obtained complete relief from their symptoms following completion of their treatments and until the first frost, when nature automatically ended their hay fever season.

Cardiac Asthma—According to Ernestine and Knowlton, cardiac asthma usually is due to sudden failure of the left ventricle, which has been damaged previously as the result of hypertension, coronary artery sclerosis or aortic valve disease. In a small group of patients with uncomplicated mitral stenosis similar attacks occur as the result of factors that increase the heart rate. When the heart rate is sufficiently accelerated the right ventricle expels blood into the pulmonary vessels more rapidly than it can pass through the narrowed mitral orifice and acute pulmonary congestion develops. Cardiac asthma due to left ventricular failure usually develops after the age of 50 years while the form due to uncomplicated mitral stenosis generally occurs in younger persons. The prognosis is poorer in the first group than in the second. In a series of forty consecutive cases of cardiac asthma on which the authors base this report the attacks were due to failure of the left ventricle in thirty-five and to the presence of uncomplicated mitral stenosis in three. Mitral stenosis was complicated by aortic insufficiency and hypertension respectively in two patients and the exact mechanism of the attacks could not be determined. The two most effective measures in the treatment of attacks of cardiac asthma are morphine and the upright position. Morphine should be administered hypodermically as early in the attack as possible, usually in doses of one-fourth grain (0.016 Gm.) and should be repeated if the patient does not appear to be improved within fifteen or twenty minutes. Cardiac asthma is attended characteristically by orthopnea. It is probable that the increase in vital capacity that accompanies the change from the recumbent to the erect posture contributes importantly to the relief experienced in the latter position. In patients with cardiac asthma due to failure of the left ventricle, morphine and the upright position may at times fail to relieve the patient sufficiently. In the absence of anemia venesection should be carried out with the removal of from 200 to 500 cc. of blood. If cardiac asthma progresses to acute pulmonary edema in spite of the administration of morphine and venesection either strophanthin or digitalis should be given intravenously. Occasionally, cardiac asthma may be relieved by the administration of glyceryl trinitrate particularly in patients with severe hypertension. A patient who has experienced an attack of cardiac asthma due to failure of the left ventricle should be treated as any other individual who presents evidence of impaired myocardial reserve. In those who have suffered more severe attacks a period of absolute rest is advisable and should be followed by strict limitation of activity. Restriction of fluids and the administration of diuretic drugs also are valuable measures. In patients with cardiac asthma due to

uncomplicated mitral stenosis it is of great importance to avoid exertion and emotional upsets. Sedatives should be given in daily divided doses to those patients who display evidence of emotional instability.

Common Bile Duct Drainage.—Carter shows that surgical drainage of the common bile duct is generally advocated for stones, cholangitis, pancreatitis and cholangitis with chronic fibrosis of the duct. The advisability of introducing a tube into the common duct is not taken up by the author, but rather the methods in use to determine that the goal of drainage has been reached. The relief of obstruction by drainage can be determined to have been accomplished when the sphincter of Oddi responds to the food test. Clamping the tube to determine the state of the sphincter of Oddi is not a necessary procedure. The presence of pus in the biliary drainage may be taken as the period of active inflammation within the duct. Daily cultures of the biliary drainage are not reliable in determining the necessary drainage period. Sedimentation of bile with crystalline formation, especially of calcium bilirubinate, should cease before the tube is withdrawn. Pancreatic ferments in the biliary drainage contraindicate removal of the tube before the sphincter of Oddi has been definitely restored to normal, as shown by the food test. Daily bile salt deter-

mination of the biliary drainage, as has been previously determined, is a distinct aid in treating liver failure in patients with a badly damaged hepatic system the result of obstruction and infection. Prolonged drainage of the common duct does not seem to be essential in most cases to meet the requirements for which drainage was instituted. Careful analysis of the biliary drainage and response of the sphincter of Oddi are essential in determining the time of drainage necessary. A careful analysis of the case during the postoperative period, with special attention to the function of the sphincter of Oddi, to the chemistry of the bile and to microscopic study for crystalline sediment and pancreatic ferment determination, is of great importance in the administration of specific postoperative medical therapy. Earlier removal of the common duct drainage tube may be possible when specific postoperative medical therapy is instituted and carried out.

Ovarian Function and Menopausal Symptoms Following Hysterectomy.—Marx and his collaborators investigated twenty one cases in which total or supravaginal hysterectomy had been performed with as much ovarian tissue preserved as seemed advisable. In one case which showed good estrogenic output only a part of one cystic ovary had been preserved. In the majority of the cases four assays were made for estrogenic substance at weekly intervals and two or more estimations for the follicle-stimulating factor were made. They conclude that there is a striking contrast between the hormone picture and occurrence of 'hot flushes' following total hysterectomy and supravaginal hysterectomy. The clinical symptoms of the menopause appear earlier and more marked after total hysterectomy than after supravaginal hysterectomy. The preservation of even a small part of the uterus seems to have a retarding and mitigating effect on the appearance of retrogressive changes in the pituitary-ovarian function and the occurrence of menopausal symptoms. The studies seem to support the theory that the uterus elaborates a catalytic principle acting on some part of the pituitary-ovarian hormone mechanism, regulating its normal balance and functional harmony. The amount of output of estrogenic substance after hysterectomy is determined more by the biologic quality than by the amount of ovarian tissue retained. Occurrence of 'hot flushes' after hysterectomy is associated in nearly every instance with an increase of gonadotropic substance and in the majority of cases with a decrease of estrogenic substance. In a few cases manifesting 'hot flushes,' average amounts of estrogenic substance and in rare instances normal gonadotropic substance may be found. On the other hand, diminution or even complete absence of estrogenic substance and increase of gonadotropic substance, occurring independently or together, are not necessarily associated with 'hot flushes'.

Squamous Cell Epithelioma of Extremities.—DeBell and Stevenson point out that considerable difference of opinion exists regarding the proper treatment of squamous cell epithelioma of the skin. At the Stuyvesant Square Hospital this type of cancer has been treated by surgical removal. The authors discuss sixty one cases of the upper and lower extremities treated in this manner. Fifty-one were on the upper limb and ten on the lower. The authors reach the following conclusions: 1 Squamous cell epithelioma is not a common type of tumor. 2 Squamous cell epithelioma is found chiefly in those of the cancer age. 3 Because of the predisposing factors, this type of tumor is more common in men. 4 By far the greatest number, forty-three, appeared on the dorsum of the hand. 5 The majority are of grade 1, histologically. 6 Duration of the lesion seems to have no relationship to metastasis. 7 Metastases to regional lymph nodes were found only in cases with larger lesions the smallest being 3 by 3.5 cm in diameter. 8 All lymph nodes showing metastases were palpable before operation. 9 Dissection of the epitrochlear lymph nodes should be considered if the lesion extends over the ulnar aspect of the hand. 10 Routine dissection of regional nodes in cases of epithelioma originating in burn scars is advocated. 11 Dissection of regional nodes should be performed in recurrent cases. 12 Although the number of cases of epithelioma on the lower extremities is not large, it appears that these are more likely to metastasize than lesions on the upper extremities. 13 There were no cases with generalized metastases. 14 Surgical removal is a satisfactory method of treatment.

Relief of Laryngeal Pain. L. B. Stott —p. 155

Climate and Tuberculosis—According to Morland climate appears to have less influence on tuberculosis mortality than such factors as racial immunity and social conditions; there is none the less some evidence that warm damp climates are associated with a relatively high tuberculosis mortality. Climatic stimulation has a definite place in the treatment of tuberculosis but care must be taken not to expose to a highly stimulating climate patients whose powers of response are inadequate. In the selection of cases careful individualization is necessary, dyspnea from diminished vital capacity, cardiac arrhythmia and nervous instability all tend to be increased with rise in altitude. No air in the world can make up for the absence of medical guidance and discipline which a well conducted sanatorium provides. With some exceptions cases with symptoms of activity are best treated in the first place at a low or moderate altitude; selected cases with adequate powers of response should subsequently be sent to higher altitudes. More sedative climates of the Mediterranean type are suitable for patients with bronchitis and emphysema with little or no tuberculous activity.

Relief of Laryngeal Pain—Stott points out that the practice of blocking the internal branch of the superior laryngeal nerve introduced by Hoffman in 1908 still retains its popularity as a method of giving relief in dysphagia. It does not however relieve the agonizing pain that shoots from the pharynx to the ear during the act of swallowing. This pain is described by nearly all patients with a tuberculous lesion in the larynx and the attitude of the victim who places his forefinger over the temporal artery and his thumb under the angle of the jaw while he regards a bowl of cold gruel is familiar to every tuberculous worker. The normal consummation of the reflex of swallowing is prevented and the obstructed action of the stylohyoid muscle is apparently responsible for the characteristic shooting pain in the ear. Six nerves—the fifth seventh ninth tenth eleventh and twelfth—all take their part in the act of swallowing and therefore it is a matter for little surprise that the blocking of one branch of the tenth fails to relieve pain during swallowing though it does anesthetize satisfactorily the laryngeal mucosa. The stylohyoid nerve however is accessible at its point of division from the inferior dental nerve as it enters the mandibular foramen behind the projection of the ligula. The terminal branch of the facial nerve to the inferior edge of the posterior belly of the digastric muscle is also of

easy access, as the anatomic relations of the digastric muscles and its attachments to the hyoid bone have definite surface markings. Thus it is possible to block the branches of three cranial nerves to the parts concerned, leaving the ninth eleventh and twelfth unaffected. That is to say, by infiltrating the neighborhood of the posterior belly of the digastric muscle with a local anesthetic and at the same time blocking the stylohyoid nerve and the internal branch of the superior laryngeal nerve on both sides, it is possible to render the act of deglutition painless without interfering with mastication or the movement of swallowing, even though occasional unavoidable blocking of the inferior dental nerve produces anesthesia of the lower lip.

Mirror Test in Pulmonary Tuberculosis—Cohen and Wood think that the test should when possible, be carried out in the early morning. The patient and examiner sit as for ordinary indirect laryngoscopy and a large size mirror—for example, No. 6—is held with its surface horizontally above the larynx. The patient is instructed to give several short barking coughs and the mirror is thus sprayed with bronchial secretion. It is then withdrawn along the roof of the mouth, care being taken to avoid brushing its surface against the tongue. Flecks of yellowish secretion of pin head size are characteristic though not typical of tuberculous expectoration. Mucoid or watery secretion usually but not invariably yields a negative result. The flat of the mirror is now applied to one end of a slide and drawn along it, leaving a thin film which is dried and stained in the usual manner. The possibility that the slide may be contaminated when the mirror has been used in a previous test is remote but careful sterilization of the mirrors is essential. Dr. Hebert has suggested to the authors that the use of the all-metal mirrors now sometimes employed for indirect laryngoscopy might be a useful safeguard. On the basis of their experiences with this test the authors reach the following conclusions: 1. The examination of secretion ejected directly from the lungs and collected by a mirror held over the larynx is a quick and convenient method of demonstrating tubercle bacilli. 2. The mirror test frequently enables the confirmation of a diagnosis of pulmonary tuberculosis suggested by history, symptoms or physical signs to be made without the delay that must occur when the patient is given a sputum outfit. Difficulties in securing the return of sputum flasks by mail are obviated. This advantage will be especially appreciated by those who work in country districts or among uncivilized communities. 3. Maltingering may be circumvented and the patient who consciously or unconsciously swallows his sputum may be induced to supply a sample of pulmonary expectoration by this means. 4. Compared with the ordinary sputum test the mirror test is more delicate and it may enable such accessory methods of examination as gastric lavage and bacterial investigation of the stools to be dispensed with. Though less delicate than the sputum concentration test it can be used when no sputum is available for that purpose.

Pulmonary Disease Due to Inhalation of Dust—Middleton discusses the disorders that develop in workers with asbestos, sillimanite China clay, talc and French chalk mica and sericite. Certain conclusions regarding the etiology of silicosis may be drawn from the consideration of the occupations in which the disease occurs. Where silicosis has been caused exposure to the inhalation of silica in the uncombined state appears to have been present. With a dust cloud of moderate concentration, the disease develops slowly and the nodules of fibrous tissue appear at certain situations in the lungs. This occurs in grinders of metal, workers on sandstone and pottery workers. When the dust contains a very high proportion of free silica in a fine state of division and the concentration of particles in the atmosphere is high, the disease tends to develop rapidly. In such cases the fibrosis retains the nodular form and develops at the usual sites but it appears also in other parts of the structure of the lungs. This has been seen in flint grinding, sand blasting and abrasive soap manufacture. When the rust of free silica is inhaled mixed with certain other kinds of dust in important amount the arrangement and distribution of the resulting fibrous tissue may be modified. Such modifications have been found in workers in coal and hematite mines. When the inhaled dust consists of silica combined with bases, as silicates, some degree of change in the pulmonary tissue appears to result. In this respect asbestos dust is unique among silicates in the prevalence and severity of the disease which it causes. The physical form of asbestos differs from that of all other industrial dusts. The fibrosis produced in the lungs by the action of silicates differs from that produced by free silica, and the types can be distinguished by radiologic and histologic means. In certain states of the lungs, for example in the presence of tuberculosis, the action of silicates may be modified.

Acute Alimentary Catarrh in New-Born—Craig shows that there is still doubt about the relative importance of infection and disturbed metabolism as causes of the diarrheas of infancy. In the Royal Maternity Hospital Edinburgh, over a period of three and one half years, there were forty-one cases of infants developing symptoms of severe gastro intestinal disturbance. Of these, seventeen occurred in minor epidemic form. An important feature was the frequency with which symptoms appeared in infants healthy at birth. There were eleven fatal cases. The term acute alimentary catarrh has been applied to the cases under discussion, as it indicates primary involvement of the gastro intestinal tract by an acute catarrhal condition, irrespective of its inflammatory nature. There was an unmistakable similarity in these cases. Signs of mild dyspepsia appeared within forty-eight to seventy-two hours of the first introduction of cows milk into the feeds. The infant became listless, the appetite less keen, and weight progress slower. The condition remained unchanged for one or two days. The stools then became increasingly loose and eventually watery in consistency and foul smelling. The stools were green or brown. Evacuations numbered from five to twelve in the day. Fever quickly followed the onset of diarrhea. It rarely exceeded 101 F. was irregular in character and fell by lysis. A progressive decline in weight commenced, vomiting once or twice in the day was common. Evidence of dehydration and toxic absorption was soon apparent. Weakness increased daily. In fatal cases death came gradually and was preceded by a period of semiconma. In those who recovered a return of the temperature to normal was the first evidence of improvement, it was followed by diminution in the number of stools and a readiness to take weak milk mixtures. With the appearance of loose stools and fever, milk feeds were discontinued, and fluids given

by mouth were limited to sweetened water and weak tea. Rectal salines were employed in only a limited number of cases, they were seldom retained and tended to aggravate any inflammation of the lower bowel. Parenteral administration of a 5 per cent dextrose-saline solution proved invaluable and was adopted as a routine. Daily subcutaneous injections of from 30 to 50 cc were given, the interval was lengthened as fluid intake by mouth was increased. In the children in whom vomiting was distressing, improvement followed the removal of mucus by a single gastric lavage. In others, similar improvement resulted from the oral administration of 2 grains (0.13 Gm) of sodium bicarbonate before feedings. Considerable benefit resulted from gentle washing out of the lower bowel when the motions were fetid or contained mucus. Liquid petrolatum (4 drachms, or 15 cc.) left in the rectum lessened the pain of defecation and the risk of excoriated buttocks. Petroleum emulsion (one-half drachm, or 2 cc.) and 2 minims (0.12 cc) of castor oil were given in mixture form three or four times daily. Brandy in small doses proved the most suitable stimulant. An attempt to reintroduce milk was made after the temperature had become normal. Prevention depends on removing risks of infection and on avoiding minor disturbances of digestion. Observations made in the present series suggest that the path of alimentary infection is often by the mouth. The view is held that the condition is primarily a result of infection. It rarely occurs in breast-fed infants. Intestinal catarrh resulting from digestive disturbance is an important factor favoring alimentary infection, and acute catarrhal conditions of the alimentary tract in the neonatal period may be responsible for dyspepsia in later infancy and early childhood.

When Is Catgut Sterile? T H Small—p 878
*Results of Short Wave Therapy K R. Speeding—p 881

Results of Short Wave Therapy—Speeding points out that the short wave type of diathermy has not yet become universally recognized, for many regard it as being identical with the older (or long wave) diathermy. The result is that it is credited with only a limited field of application and that many patients who would benefit considerably from the therapy are treated by other methods on the assumption that the contraindications are the same as those of long wave diathermy. A brief description of the results of short wave therapy in twenty-five cases is given. The first patient had a variety of neuropathy together with moderately advanced rheumatoid arthritis, mucous colitis, vasopharyngeal catarrh and purulent tonsillitis. Instructive features of the case include the tonsillar reaction, suggesting that the therapy may be of value in many of these conditions, and the improvement of the catarrh. Among other conditions in which the author resorted to the short wave therapy were pelvic peritonitis, supra-orbital neuralgia, psoriasis, chronic inflammation of the semilunar bone, bleb formation over the base of the great toe, furunculosis of the leg, chronic mucosal thickening of both antrums, pansinusitis, hay fever, rheumatoid arthritis, monarticular osteo-arthritis, spondylitis, asthma, pulmonary fibrosis, periduodenitis, otosclerosis, peritarticular inflammation, synovitis and paronychia. In discussing the technique the author says that the short wavelength (6 meters or less) was not found to have any special value, so a longer one (24 meters, approximately) was adopted and appeared to be quite suitable for practically all purposes. One of the valve types of apparatus was used for the work as the spark gap machine was not considered to be efficient enough, especially when depth effect was particularly desired. Many different types of electrode were investigated. For general use the pad was found to be satisfactory. Its insulation may be composed of cloth surrounded by rubber, thus avoiding any likelihood of electrical shock and the possibility of any deep seated burn. For the majority of diseases a time of approximately ten minutes or less is suitable for the initial application. The dosage may be steadily increased after this but it is not considered advisable to allow the production of any reaction that is more than

temporary in its nature. In estimating the effects of the treatment one is impressed with the fact that in many conditions the response is poor, while in others the improvement is rapid and persistent. Thus it is obvious that short wave therapy cannot be regarded as a universal cure. But it is equally obvious that the indications for its use in certain cases are pronounced, and the ease of application combined with the freedom from any harmful results should commend the method both to the physician and to the patient. The advantages of roentgenologic control are mentioned.

*Study of Variations of Blood Cholesterol M. Lévy and L. Gally.—p. 1147

Study of Variations of Blood Cholesterol—Levy and Gally studied the blood cholesterol of patients suffering from hyperthyroidism during the course of treatment with roentgen rays. They believe that the level of blood cholesterol in patients having hyperthyroidism is as important as the clinical course and the basal metabolic rate. Thus, for example, the rapid and ample increase in the level of the blood cholesterol accompanying the clinical signs of improvement and the tendency toward the return to normal of the basal metabolic rate can indicate the discontinuance of further roentgen treatments of a thyroid gland. Similarly, when roentgen treatment is unsatisfactory, an early and rapid demonstration of this fact can be made with the aid of cholesterol determination.

Milk as Source of Vitamin C E. Stoerr.—p. 427

Treatment of Thrombopenic Purpura by Phenylhydrazine—Wallgren observed four cases of purpura treated with phenylhydrazine, and the reactions differed widely. In most instances there was a considerable increase in the number of platelets accompanying the first administration of phenylhydrazine. This increase in platelets might or might not be associated with improvement in frequency and severity of hemorrhages. Cumulative effects were observed. It was also noted that a solution of phenylhydrazine rapidly loses its effectiveness, and therefore a freshly prepared solution should be used each time. In general the hemolytic effects of phenylhydrazine appear earlier than its irritative action on the osseous tissues (notably the multiplication of platelets). Therefore the increase in the number of platelets is almost always accompanied by a decrease in the number of erythrocytes. With the results of phenylhydrazine on this type of purpura so uncertain and the likelihood of producing hemolysis and anemia, the author believes that this medication should not be employed in the treatment of thrombopenic purpura.

*Studies on Reticulocyte Behavior in Typhoid B. Jochweds and A. Szejnberg.—p. 833

Reticulocytes in Typhoid—Jochweds and Szejnberg attempted to study the function of the osseous medulla in typhoid by observing the behavior of the reticulocytes in the peripheral blood. Sixty-one patients (thirty-three males and twenty-eight females) ranging in age from 14 to 50 years were thus observed. During the second and third weeks of the typhoid the reticulocytes were below 3 per thousand in 73 per cent of

the cases, in the others they oscillated between 3 and 9 per thousand. The level was not much increased in the fourth and fifth weeks and it was not until the following weeks that a notable augmentation of reticulocytosis, from 7 to 26 per thousand, was noted. The common stimulants of the osseous tissue, such as hemorrhages, injections of horse serum, liver extracts and blood transfusions, produced a rapid and lasting increase in the number of reticulocytes. This fact suggests an inhibition of the osseous tissue rather than a complete suppression. Furthermore, reticulocytosis was markedly diminished in relapses of typhoid.

*Experiences with Permanent Suction Drainage of Duodenum in Ileus and Peritonitis R. Howald.—p. 799

Research on Action of Sedatives of Sympathetic Nervous System in the Clinic M. Monnier and J. Sterne.—p. 801

Progress in Experimental Cancer Research K. Ullmann.—p. 803

Experiences with Permanent Suction Drainage—Howald shows that in ileus the gastric stasis is generally counteracted by lavage of the stomach. This method, although giving considerable relief in ileus as well as in peritonitis, has the disadvantage that its efficacy is of only short duration. In order to make the effect of this treatment more lasting, permanent gastric drainage by means of the usually introduced tube has been tried. The author points out that, whereas in German clinics the permanent gastric drainage is usually employed in peritonitis and in postoperative disturbances in the intestinal passage, some American clinics resort to this method also in the nonperitonitic forms of ileus, passing the tube down into the duodenum. In describing the method, he says that at his clinic in Basel the treatment is done with Pratt's modification of Wangensteen's apparatus. By the continuous suction, the stomach and the upper portions of the small intestine are gradually evacuated. Corresponding to the antiperistaltic waves of the small intestine in ileus, the evacuation takes place at intervals. Suction drainage is most effective in simple ileus of the small intestine, particularly when it is acute and incomplete, that is in all conditions in which otherwise a fistula of the small intestine is made. Moreover, the method can be used with hope for success also in subacute ileus and in other intestinal obstructions be they in the small intestine or in the colon. The author cites the histories of two cases in which beginning ileus could be counteracted by suction drainage alone. The method is helpful also in the later stages of ileus, as preparation for the operation because the suction drainage not only effects a mechanical relief but also has a detoxicating effect. To be sure it is necessary to keep the patient under careful observation, and, if there are signs of strangulation with a disturbance in the blood perfusion of a portion of the intestine, the operation cannot be postponed. On the basis of additional case reports, the author shows that permanent suction drainage is helpful also in postoperative intestinal atony and in all peritonitic conditions, particularly in cases of perforated appendix. In order to prevent dehydration in patients undergoing suction drainage fluids must be administered by the parenteral route (at least 3000 cc within twenty-four hours). To counteract the depletion of the chlorides physiologic solution of sodium chloride or Ringer's solution should be infused. In addition to this 5 per cent solution of dextrose should be given. In peritonitic conditions opiates should be prescribed in order to inhibit peristalsis. Hot compresses on the abdomen are advisable particularly in inflammatory conditions. The author says that recently suction drainage of several days duration has been recommended also in preparing patients with gastric ulcer or carcinoma for the operation.

Estrogen in Treatment of Gonorrheal Vulvovaginitis—Escardó and Salzman review the literature on the development of endocrine therapy and consider the indications for administration of estrogen, the safety of the treatment and the doses, routes of administration and mechanism of action of estrogen in vaginal infections. They report the results of the treatment in gonorrheal vulvovaginitis in girls ranging in age from 2 to 10 years. The treatment was successful in seven of the eight patients treated. The authors conclude that gonorrheal vulvovaginitis in little girls is controlled by the beneficial effect of estrogen on the infantile vulvovaginal mucosa. The dose should be determined in each case by the reaction of the mucosa to the estrogen. The mucosal reaction is verified by making periodic bacteriologic and cytologic examinations of the mucosal tissues in vaginal smears. Oral administration is easier than that of other methods, but the results are good by either route. The general effect of estrogen on the organism of the patient seems to be harmless. The method is in the experimental phase. True conclusions as to its value and effects will result only from prolonged studies in a large number of cases. Gonorrheal vulvovaginitis in small girls has been resistant to the several treatments used in the past. The estrogen treatment seems promising.

Recurrent Benign Spontaneous Pneumothorax—Castex and Mazzei summarize the cases of recurrent benign spontaneous pneumothorax reported in the literature up to the present time and report three cases seen in their practice in a group of twenty cases of benign spontaneous pneumothorax. The condition develops with preference in young men. The symptoms are those of nonrecurrent benign spontaneous pneumothorax. It is the result of the tearing of so-called subpleural blebs, the rupture of which is caused by an exaggerated pressure during an effort. The subpleural blebs form themselves mechanically, at the level of the weaker or slightly altered areas of the lung, at the time of gaseous overdistention at that level. This interpretation is supported by the data given by the roentgen and anatomopathologic studies of the lung in this condition as well as by results of experiments. In all cases of benign spontaneous pneumothorax it is advisable to investigate, by means of the roentgen study of the lung, the presence of fine ring shadows at the contours of the visceral pleura which represent subpleural blebs located at that level. In the roentgenograms of the lung of one of the authors' patients, who was suffering from recurrent benign spontaneous pneumothorax, the shadows given by the subpleural blebs were evident in all the consecutive roentgenograms. The prognosis and treatment of the condition are the same as those of nonrecurrent benign spontaneous pneumothorax.

Cavernous Sinus and Oculodental Venous Connections. L. E. Longinotti—p. 1905

Results of Specific Serotherapy in Multiple Sclerosis—The treatment used by Carulla and Zunino consists in weekly subcutaneous injections of from 2 to 3 cc of hemolytic serum of rabbits previously immunized with the blood of the patients. The authors report results in three cases, in one of which the evolution of the disease has been controlled for more than three years. In this case the discontinuation of the treatment for three months, after a year and a half, resulted in recurrence of the disease, which was controlled by further treatment. The best results are obtained when the treatment is given early, before establishment of grave nervous lesions. It is advisable to give the treatment indefinitely, because its discontinuation generally results in recurrences.

Takata-Ara Reaction in Internal Diseases—Boccia and Gamalero used the Takata-Ara reaction in several internal diseases. The test gives positive results in all cases of atrophic cirrhosis and neurosyphilis and negative results in liver cirrhosis and several internal diseases of different nature. The results of the test are variable in pathologic processes of the biliary tract and in tuberculosis. In these conditions the test has neither a diagnostic nor a prognostic value. In cancer (whether or not developed in the liver) and in cachexia the results may be positive or negative. The technique of the Takata-Ara reaction is simple. Combined with other similar tests it can be of diagnostic value in certain internal diseases. However, it is not specific. Because of the small number of cases in which the authors have made the test, their article is a preliminary note and their conclusions are not definite, but they are still experimenting.

Blood Picture in Chronic Glomerular Nephritis—Miske and Otto direct attention to the unusually pale appearance of patients with glomerular nephritis. They observed an anemia in 44 per cent of the cases of chronic glomerular nephritis in which there was no essential disturbance in the renal function. The hemoglobin content was generally about 70 per cent. The number of erythrocytes was on the average around 373 millions. As the urea values increased, the anemia became more severe. The same relationship was discovered between the anemia and the rest nitrogen. The increase in the uric acid content of the blood usually preceded the changes in the other blood values and in the degree of anemia. Leukocytosis of a milder degree was observed in 54 per cent of these cases. In the cases of chronic glomerular nephritis that were accompanied by renal insufficiency, anemia had an incidence of

90 per cent. The hemoglobin content was as a rule around 56 per cent, the number of erythrocytes was 316 million and the average color index was 0.88. In these patients also an increase in the retention of the urea was accompanied by an exacerbation of the anemia. The highest uric acid values were found in uremia and in cases in which the hemoglobin values were around 50 per cent. The indican reaction became stronger as the anemia increased. The xanthoproteic test showed a behavior similar to that of the indican test. The leukocyte values were increased in 60 per cent of the cases and were never reduced. However, there was no relation between the number of leukocytes and the anemia. In genuine contracted kidney, the transitional cases showed increased hemoglobin and erythrocyte values. Patients with decompensated renal function showed anemia, the development of which was approximately parallel to the retention of the urinary substances. In the patients with anemia, the indican and xanthoproteic reactions were positive in 64 per cent whereas in those without anemia they were positive in only 21 per cent.

Atypical Azurophilic Granulation in Megaloblasts—Jones says that during the past several years he has been making an intensive study of the megaloblast normoblast problem. One of the facts that have been stressed constantly in morphologic hematology is that the first developmental stages of the hemoglobiniferous series are always devoid of any type of granulation. Apparently the appearance of granulation in the cytoplasm of hemoglobiniferous cells is rare or else it would have been described before. While this investigation was in progress, Segerdahl reported granulation in the cytoplasm of early megaloblast stages of pernicious anemia bone marrow. Since the author's observations do not coincide with those of Segerdahl and since there is considerable theoretical importance attached to the finding of granules in the cytoplasm of young hemoglobiniferous cells, he believes that an accurate description of the granules should be made and due consideration given to the bearing this observation has on theoretical hematology. He describes his observations and points out that Downey cannot agree with any of the proposed theories, since he finds that azurophilic granulation is not necessary for granulocytic development and maturation. He observed cases of myelogenous leukemia in which the granulocytes are developing from myeloblasts without any azurophilic granulation. The author's observations tend to support Downey's views concerning the significance of azurophilic granulation. Certainly the finding of azurophilic granulation in the early megaloblast stages dispels any concept that they represent a temporary differentiation of the stem cell along granulocytic lines. The presence of azure granules in prophilic and basophilic megaloblasts may be indicative of rapid proliferation and differentiation toward the hemoglobiniferous series, in which case the differentiation may have been so rapid that the azurophilic granules did not have time to disappear before reaching the promegaloblast stage. No such condition exists normally in the normoblastic series so that their presence must be interpreted as being atypical and pathologic. The collection of azure granule remnants into a juxtanuclear position may be similar to the pathologic alteration of azure granules in the form of Auer bodies. These granules do not appear in the megaloblasts in every case of pernicious anemia. It might be thought that they are due to technic. At any rate, regardless of the obscure mechanism which causes the rare occurrence of these granules in megaloblasts, the finding of azurophilic granules in the early forms of megaloblasts further substantiates the author's observation concerning the origin of the megaloblastic series from the myeloblast in pernicious anemia bone marrow during relapse.

- Percutaneous Arteriography as Therapeutic Method A. Bentel and O. Klein—p. 899
- Scarlet Fever and Angina F. Schlei—p. 902

Influence of Vitamins A and C on Glycosuria—Roller studied the influence of vitamins A and C on the glycosuria of patients with diabetes mellitus. His observations on the regulatory effect exerted by these vitamins seem to explain the

favorable results that are obtained with certain empirically established diets of the preinsulin era. A reduction of the vitamin A vehicles, such as eggs, butter and cream, and of vegetables that contain vitamin A results in a reduction of the glycosuria or permits the intake of larger quantities of carbohydrate. Moreover, it is known that a diet containing large amounts of protein promotes the action of vitamin A, whereas a diet deficient in vitamin A furthers the development of A avitaminosis. Consequently the restriction of the protein content of the diet signifies a reduction in the vitamin A action, which in turn results in a lessening of the glycosuria. Thus not only the exclusion of the vitamin A vehicles but also a reduction in the proteins permits the intake of greater amounts of carbohydrate without increased glycosuria or insulin requirements. The glycosuria can be still further reduced if the diet provides generous amounts of vitamin C, or if vitamin C is given in the pure form.

Percutaneous Arteriography as Therapeutic Method—Technic—Beutel and Klein palpate with the finger below the inguinal fold the site of the most intense pulsation of the femoral artery and puncture here at an angle of 45 degrees with an injection needle. At first the injection needle is connected with an empty syringe, but after the arterial wall has been penetrated and the plunger of the empty syringe is moved by the arterial blood stream a 20 cc. injection syringe filled with the warmed contrast medium is attached to the needle. In order to be certain that the point of the needle is actually in the lumen of the artery, some blood is permitted to enter this second injection syringe. Then the entire quantity of the contrast medium is injected in from ten to fifteen seconds. Following the injection, a compression bandage is put on and a sand bag is placed on the site of the puncture. The patient continues to lie down for several hours, and after three or four hours he is usually able to get up again. In some patients as many as thirteen injections were made. The authors cite the history of a typical case and assert that in a number of other cases they obtained similar favorable results. They gained the impression that in some cases the injection treatment will permit a postponement or entirely prevent the amputation of an extremity. In discussing the action mechanism of this treatment, they suggest that the injected substance exerts not merely a mechanical but a pharmacodynamic action on the circulation and the blood perfusion of the vascular region in question. Capillaroscopy disclosed a considerable dilatation of the cutaneous capillaries, and the patients experienced a burning sensation of heat.

Pleurisy During Childhood—Vogt says that if the stasis transudates that occur in all age groups are disregarded there remain for the period of childhood only two types of pleural disorders, the serous and the suppurating pleuritis. Empyema develops chiefly during the first few years of life whereas serous pleurisy chiefly attacks children over 5 years of age. Both of these disorders are related to pneumonia. In nearly all cases of pneumonia that react to the pleura a serous exudate of the pleura develops. To be sure, these serous exudates that accompany practically every pneumonia are usually so slight that they escape detection by the usual methods of examination. Extensive serous exudates are the exception after pneumonia. The so-called idiopathic pleuritis has connections with tuberculosis for it has been observed that from 30 to 50 per cent of the patients who pass through a serous pleurisy succumb to a progressive tuberculosis within the following four years. However in children the danger is not so great as in adults. The author considers it justified to refer to idiopathic pleurisy as "paratuberculous" pleurisy but emphasizes that this term indicates only that the disorder develops on the basis of a tuberculosis and is not a tuberculosis of the pleura in the anatomical sense. In the treatment of serous pleurisy the question regarding the evacuation of the exudate by puncture is of vital importance.

tance. Evacuation becomes necessary as soon as the exudate becomes so extensive that it causes a displacement of the mediastinum with dyspnea and circulatory disturbances. Aside from this, it has not been proved that evacuation shortens the course of the disease. As long as there is still fever, the exudate usually reappears. Following subsidence of the fever, the exudate is usually rapidly absorbed without an intervention. The author warns against too early beginning of the respiratory exercises and too early getting up. The knowledge that serous pleuritis not connected with pneumonia are often related to tuberculosis makes a careful supervision necessary even after the serous pleuritis has subsided. The author points out that occasionally empyemas of the pleura are observed in new-born infants or in older infants as a partial manifestation of a generalized sepsis or a metastasis of a suppurating inflammation in the abdomen. However, the greatest majority of the pleural empyemas develops in connection with pneumonia. The younger the child, the more often is the empyema a complication of pneumonia. Since lobar pneumonias reach the pleura more frequently, it is understandable that they are more often complicated by empyemas than are bronchopneumonias. Particularly in nurslings, the empyema is often masked by the simultaneously existing pneumonia, so that in some cases they fail to be recognized until necropsy. Empyema in young children has a high rate of mortality. Of course, it is often impossible to determine whether the empyema or the accompanying pneumonia caused the death. In discussing the treatment of empyemas the author says that the mortality rate has been reduced since it was realized that a resection of ribs or a wide opening of the pleural cavity must be avoided as long as the pneumonia has not completed its course. Avoiding the resection of the ribs during the first stage of the empyema is not identical with a failure to remove the pus from the thorax, for puncture as well as suction may be resorted to. In some cases these measures are adequate for a cure and at least bridge over the time during which resection of ribs would be dangerous.

Corrosive Esophagitis—Markow made careful observations on the development of corrosive esophagitis, beginning with the first few hours after poisoning with the caustic substance and continuing to the end of the first, second or fifth year. The material consisted of sixty cases. He describes the histologic aspects of acute and chronic corrosive esophagitis, the peculiarities of the reparative process and the macroscopic aspects. He stresses the great variety of the pathologic-anatomic aspects of corrosive esophagitis, not only in the different cases but also during the several stages in the same patient. He found that in many cases the corrosive changes of the esophagus are so superficial that they hardly require local treatment whereas in other cases they are so deep and extensive and the general intoxication is so severe that local treatment is only a useless torture for the patient. In still others the inflammatory process and the subsequent chronic ulcerations lead to such hard and extensive scars that no improvement can be expected from local treatment.

Therapeutic Experiments with Vitamin A in Cancer—Because their animal experiments had demonstrated that the growth inhibiting action of vitamin A becomes manifest only in epithelioma but not in sarcoma of mice, Lustig and Wachtel limited their therapeutic experiments on human cancers to histologically verified epitheliomas. They used a vitamin A preparation which contains 40,000 biologic units in 1 cc. They apply the vitamin in the form of compresses and subcutaneous injections. If the vitamin is applied in the form of compresses it is used as an emulsion, which is obtained by mixing it with a colloidal copper preparation. In case of subcutaneous injections,

0.4 cc. of the copper colloid and the corresponding dose of vitamin are drawn into the syringe and, without mixing, are injected together. At first the authors treated superficial tumors (cutaneous epitheliomas and mammary carcinomas) applying the vitamin by means of compresses. Under the influence of this treatment the ulcerated surface becomes smaller, new epithelium grows in from the periphery, and the bottom of the ulcer becomes clear. These therapeutic effects were limited to the part of the tumor to which the treatment had been applied, the untreated portions remaining unchanged. Distant metastases likewise remained uninfluenced. But although the vitamin A compresses exerted a favorable effect, a complete cure of the cancerous ulcerations was not obtained until radium treatment was employed. Treatment with vitamin A was found especially helpful in cases in which a torpid ulcer remained after radium treatment. In subcutaneous administration of vitamin A, restriction to a certain dose is necessary in order to avoid the undesirable symptoms of hypervitaminosis. The threshold of tolerance for this mode of administration is between 100,000 and 120,000 biologic units. The authors begin with an injection of 40,000 units and twenty-four hours later inject another 20,000 units. If these injections produce an improvement a third injection of 20,000 units is made two days later. If this is followed by further betterment, an additional 20,000 units is given three days later. New series of injections should not be given until at least five or six weeks has elapsed. The authors conclude that, although vitamin A fails to effect complete cure of cancer its palliative action is sufficiently well established to justify its application as an adjuvant to other therapeutic methods.

Treatment in Drug Addiction—Weger and Amsler cite experimental evidence to the effect that in animals morphine addiction can be retarded by the administration of calcium and hastened by chronic intoxication with oxalic acid. They also determined that the breaking of the drug habit can usually be hastened by the administration of calcium. However, in view of occasional failures of calcium medication, it was thought that a deficiency in vitamin D might also play a part and so the authors decided to make further investigations. On the basis of their results, they again recommend the use of calcium in the treatment of drug addiction. They consider the intravenous injection of calcium gluconate the best mode of administration. They also advise supplementing this calcium therapy by measures that promote the vitamin D metabolism (phosphorus, cod liver oil and so on). It is suggested that, in the treatment of addiction to alcohol, calcium-vitamin therapy might likewise be helpful.

Experiments on Antithyroid Protective Substances—After citing earlier investigations on the antagonism between thyroxine and antithyroid substances, Fellinger and Pfleger describe further experiments. They first determined that the administration of iodine to guinea-pigs stimulates the thyroid of these animals. Their further object was to determine whether this iodine action on the thyroid could be influenced by the antithyroid protective substance that they themselves had obtained from human blood by means of ether extraction. They found that the administration of this substance generally weakened or entirely prevented the activation of the thyroid by means of iodine. Tests on rats likewise revealed an influence of the antithyroid protective substances on the thyroid. The authors conclude that their experiments furnish further support for the assumption that the ether soluble antithyroid substances of the blood have an inhibiting effect on the thyroid. The question whether these substances act on the thyroid directly or by way

of its regulatory mechanism has not been answered as yet, however, the experiments indicate that the antithyroid protective substances influence not only the thyroid hormone but also the gland or its regulatory mechanism.

Multiple Osteomyelitic Foci After Typhoid—Chatzelson reports the clinical history of a girl, aged 20, who had abdominal typhoid that necessitated confinement to bed for five months. During this time the patient complained of intermittent pains in both legs. When she got up she complained of continuous severe pains in the lower third of the right leg where a swelling had developed. Roentgenoscopy disclosed several osteomyelitic foci along the tibia. An operation was performed and after that the patient felt improved. However, less than four months later the patient was again hospitalized on account of pain and swelling in the right temporal region. An osteomyelitic process of the frontal bone was thought of and roentgenoscopy corroborated this diagnosis. On the following day an operation was performed and it was found that the osteomyelitic process had caused an epidural abscess. The patient recovered. In order to prevent a renewed flare up of osteomyelitic foci, the author decided to try blood transfusion. The first transfusion caused extremely severe reactions and the patient had to undergo two other surgical interventions for the treatment of osteomyelitic foci. Then further blood transfusions were tried the reactions from them being milder each time. Whether these additional blood transfusions will prevent the flare up of other osteomyelitic processes cannot be stated as yet.

*Differential Diagnostic Value of Symptoms During Course of Liver Diseases A Steinhardt—p 664
Hypertension from Point of View of Social Position W Łuczynski—p 665

Diagnostic Value of Symptoms in Liver Diseases—Steinhardt calls attention to the value of the symptoms of palate discoloration in the diagnosis of diseases of the liver. In the first stage the discoloration is oval and of about the size of a large bean on each side of the median line. In the second stage there is complete discoloration of both sides of the soft palate it being pale, dimly yellowish and diffuse. This color signifies a subacute condition of the disease. In the third stage the yellow is still darker and dimly reddish. These three stages point to a disease of the liver and associated organs such as the heart and lungs. In chronic diseases of the liver the symptom is not so important but in acute stages of any other disease the sudden appearance of this symptom is alarming. In a case of pneumonia, which progressed normally, the sudden appearance of palate symptoms made the author change the routine of treatment. The disappearance of the symptoms served as a sign that the patient was on the road to improvement. In short the appearance on the soft palate of the yellowish discoloration in three stages may serve as a warning symptom and have an important meaning for the differential diagnosis and prognosis.

Blood Sugar Curve in Water Tolerance Test P O Buch—p 557

Epidemic Hepatitis—Wickström concludes that epidemic hepatitis is a specific infectious disease. From 1932 to 1935 it occurred in eastern Nyland with varying intensity, with a morbidity of up to 58.4 per cent. During the epidemic the contagion index was considerably increased, owing presumably to increase in virulence. Several cases in the same family were common. In some schools the morbidity rose to 43.2 per cent. The infection is thought to have been transferred mainly from person to person. The period of incubation is usually from three to five weeks. There are seasonal variations as in droplet infection, with maximum in December and February. Those who have had the disease apparently acquire immunity.

Acute Myocarditis—Kjærgaard reports ten cases of acute myocarditis which did not originate as complications in inflammatory rheumatism, diphtheria or sepsis. In one of the six cases connected with ordinary croupous pneumonia, in a man aged 57, transient atrial flutter shown by electrocardiogram, was successfully treated with digitalis. In the second case, with perhaps more grave myocardial disturbance, treatment with digitalis was ineffective. In the next three cases of milder pneumonia, without arrhythmia the myocarditis was discovered on electrocardiography. In the sixth instance in a man aged 32 who died from bilateral croupous pneumonia, the electrocardiogram was normal but microscopic examination of the heart revealed acute myocarditis. In one of four cases of apparently primary myocarditis in patients ranging in age from 26 to 36 the myocarditis proved to be the first clinical sign of a rheumatic infection, in the second it was due to an overlooked typhoid together with later streptococcal infection and in the last two cases, both fatal, no cause other than general nonspecific infection was found in life or on necropsy. The author stresses the significance of electrocardiography in patients who have had even a slight infection and feel short of breath. He asserts that the postmortem establishment of acute myocarditis in spite of a normal electrocardiogram emphasizes the importance of a long period for convalescence after pneumonia and that an abnormal electrocardiogram in a convalescent always indicates rest in bed and a longer time for convalescing particularly if the patient does hard labor. The course of these acute myocarditides is always protracted even the milder cases requiring three months for recovery. Some cases now diagnosed as idiopathic hypertrophy are thought to depend on earlier acute myocarditis and most of the cases of chronic myocardial degeneration seen in younger persons to be the result of overlooked acute myocarditis. The prognosis is always doubtful. Since acute myocarditis may be the first sign of a specific rheumatic disorder careful selective treatment is advocated in all etiologically doubtful cases. Digitalis is generally believed to have only a slight or even a harmful effect in acute myocarditis. The success of treatment depends on early recognition, long rest in bed and control.

HYPERSENSITIVENESS TO COLD

WITH LOCAL AND SYSTEMIC MANIFESTATIONS OF
A HISTAMINE-LIKE CHARACTER ITS AMEN-
ABILITY TO TREATMENT

BAYARD T HORTON, MD

GEORGE E BROWN MD

AND

GRACE M ROTH BS

Fellow in Physiology the Mayo Foundation

ROCHESTER, MINN

Danger lurks at the bathing beach for those who are hypersensitive to cold, but the danger can be eliminated by adequate desensitization. We do not pretend that, scientifically, this is the most interesting implication of the present report, we do believe that now, with summer almost at hand, it is the most immediately applicable feature of our work.

The study represents a clinical and experimental investigation of twenty-two cases seven of which have been previously reported, illustrating the various phases of hypersensitiveness to cold. This constitutes the entire group of such cases observed at the Mayo Clinic during the past ten years. The ages of these subjects ranged from 15 to 59 years. Eleven of the subjects were females and eleven were males. With few exceptions they appeared to be in good general health, some were even robust. One subject also had osteitis deformans¹ and one a hyperfunctioning adenomatous goiter with hyperthyroidism. Routine general examinations and laboratory tests gave essentially negative results. The Wassermann reaction of the blood was negative in each instance.

These patients exhibited abnormal local and systemic reactions following exposure to cold, and the systemic reactions were so striking as to constitute a clinical entity. Symptoms had been present for from one month to thirty years and consisted for the most part, of urticarial wheals over the face, neck and hands and occasionally over the feet, thighs and trunk. Urticarial manifestations invariably followed exposure to a cold wind, cold water or a cold environment. A number of the patients had swelling of the lips and one had dysphagia following ingestion of cold water or ice cream.

Of the twenty-two subjects, all manifested local reactions and fourteen in addition, had well developed systemic reactions. Eleven of these fourteen subjects had attacks of syncope following exposure to cold, and some of them were unconscious for more than two hours. No convulsions had been observed. Nine of

these eleven subjects had collapsed after swimming and four of them had had to be rescued from the water, two having been unconscious for more than an hour after being rescued.

Three of the eleven patients were particularly interesting. An attack of syncope was reproduced experimentally on one of them, a strong man aged 22, who was permitted to sit in a bath tub with the hands, legs and thighs immersed in water at 11 C (51.8 F) for four minutes. Shortly after leaving the room he collapsed. Three minutes later he recovered sufficiently to be able to walk. The second of the three patients, a man aged 52, had collapsed on the street while walking against a cold wind. The third, a healthy man aged 42, had partly walked and partly run a distance of four blocks against a cold wind, with the temperature at 30 degrees below zero, in order to catch a bus. He rode on the bus for a few blocks, got off and then walked about one block before going into a heated building. A few minutes after he entered the building his knees became weak and he collapsed, he was unconscious for about forty minutes. He vomited several times and was taken to a hospital, where he remained for a day. He did not recover his normal strength for about a week, and even then his stomach did not feel entirely normal. A year previously this patient had collapsed after swimming, but he had made a complete recovery from the systemic reaction in twenty-four hours.

These local and systemic reactions suggest those produced by injection of histamine or a histamine-like substance.¹ Our studies allow more than a speculative statement on the probable nature of these reactions. Physical agents such as cold probably permit the release of chemical substances from the tissue cells resulting from increased permeability. Histamine has been found in the normal skin of human beings, and Harris² has estimated the amount to be 10 mg per kilogram of tissue, the exact amount varying somewhat for the different regions of the body. Histamine is a normal constituent of liver, gastric mucosa and skeletal muscle and is probably a widely distributed³ constituent of all animal tissues. As a result of cold, it seems that histamine is released and that this, in addition to producing the usual urticarial changes locally, attains sufficient

concentration in the general circulation to produce reactions in every way comparable to those obtained when it is injected into the body

Local and systemic reactions were reproduced by immersion of the hand in water at 8 C for a period of six minutes (figs 1 and 2). The local effects on the skin consisted of pallor during the period of exposure, followed by redness, swelling and increased local temperature on removal of the hand or exposed part from the cold environment. After a latent period of from three to six minutes a characteristic systemic reaction developed, consisting of flushing of the face, a sharp fall in blood pressure, a rise in pulse rate, a tendency to or the actual development of syncope and transitory recovery in from ten to fifteen minutes. If a tourniquet was applied so as to cut off the venous return from the hand or the supply of arterial blood to the hand before the hand was immersed in the cold water, and if the tourniquet was kept on for an additional period after removal of the hand from the cold environment, the systemic reactions did not occur so long as the tourniquet remained around the arm (fig 3). When the tourniquet was then released the systemic reactions were more severe, frequently lasting three times as long as when the tourniquet was not used. The reaction occurred from one to two minutes after release of the tourniquet, whereas without the tourniquet in the average case the reaction occurred in from four to six minutes after removal of the extremity from the cold environment.

This observation is extremely important, for it seems to eliminate definitely a reflex basis for the systemic response. The procedure was repeated several different

Fig 1—Appearance of the right hand of a woman aged 26 after it had been immersed in water at 8 C (46.4 F) for six minutes. The hand was markedly swollen and the patient was unable to close it.

times on five different subjects and with identical results. These observations have been confirmed by Harris, Lewis and Vaughan⁴ and by Bray.⁵ It suggests that

a chemical substance which caused a histamine-like reaction was produced in the skin following exposure to cold and that an accumulation of this substance in the hand in sufficient concentration, when suddenly released into the general circulation, produced a greatly exaggerated systemic reaction. Local swelling of the hand can be reproduced by the intra-arterial injection of

Fig 2 (same patient as in fig 1)—Histamine like systemic reaction following immersion of hand in water at 8 C. for six minutes.

from 0.1 to 0.15 mg of histamine, the swelling is distal to the point of injection. The systemic reaction can be accurately reproduced by the subcutaneous administration of 0.5 mg of histamine. Eustis⁶ was the first to produce urticaria experimentally by means of histamine.

Patients are unable to distinguish between the systemic manifestations produced by immersion of the hand in cold water and those produced by subcutaneous injection of histamine. Obviously it is not always possible to pursue an investigation to an end point when the subject investigated is a human being. On six subjects however, the exact clinical syndrome that followed immersion of the hand in cold water was reproduced by administration of known amounts of histamine. Changes in surface temperature were studied. In one case, that of a woman aged 45, a severe reaction was induced following immersion of the hand in cold water and at the height of the systemic reaction the temperature of the cheek was 34.4 C, an increase of 4.2 degrees C. Later in the same case the surface temperature of the cheek was 35.3 C, an increase of 3.9 degrees C following subcutaneous administration of 0.35 mg of histamine.

Electrocardiographic studies were carried out in two cases before, during and after the general reaction. At the height of the systemic reaction there was an inverted T wave in lead 3 which was absent during the period of control.

The response on the part of the gastric acids is interesting in attempting estimation of the quantity of histamine-like substances liberated from the skin and

subcutaneous tissues of the exposed part. We have not seen similar reports in the literature. In one case, that of a woman aged 59, before the hand was immersed in water at 96 C analysis of the gastric content disclosed no evidence of the presence of free hydrochloric acid and the total acidity was 20 when titrated with tenth normal solution of sodium hydroxide (fig 4). No change in gastric acids was observed while the hand was in water. When the gastric secretion was removed at the height of the systemic reaction, the value for free hydrochloric acid was 54 and the total acidity was 66. Similar values were observed one year later in the same case on repetition of the same procedure. After the patient had completely recovered from this systemic reaction the values for gastric acids were: free hydrochloric acid, 0, total acidity, 38. After subcutaneous

although attempts to isolate histamine or a histamine-like substance from the blood stream at the height of the systemic reaction thus far have been unsuccessful. Moreover, we have not been able to isolate histamine from the blood stream at the height of the systemic reaction produced by subcutaneous administration of 1 mg of histamine.

TREATMENT

These patients are amenable to treatment. Systemic desensitization to cold can be accomplished by having the patient immerse a hand in water at 10 C for from one to two minutes twice a day for from three to four weeks. This, we believe, is sufficient to immunize the average subject, even patients who had swelling of the lips and tongue following the eating of ice cream, in addition to local swelling of the hands and face from

* Rescued from the water

† Paradoxical reaction with hemoglobinuria

administration of 0.5 mg of histamine, without exposure to cold, the value for free hydrochloric acid was 18 and the total acidity was 48 (fig 5). In another case, that of a man aged 52, the value for free hydrochloric acid was 56 and the total acidity was 90 before the hand was immersed in cold water, at the height of the systemic reaction the value for free hydrochloric acid was 86 and for total acidity, 108. The response on the part of the gastric acids is of interest in estimating the quantity of histamine present. As is shown by our studies, greater quantities of gastric acids were obtained by the cold applications than by the administration of 0.5 mg of histamine.

Unfortunately, there are not available at present chemical methods of sufficient accuracy and sensitivity to allow the exact quantitative estimation of the histamine-like substance in the blood during these studies. Until the chemical demonstration has been made, it is impossible to determine the chemical nature of the substance that is responsible for this abnormal reaction to cold. The physiologic responses strongly suggest that the substance is similar to histamine,

exposure to a cold environment, have obtained complete relief by this method of treatment. Also, by daily immersion of the hand in cool water, starting at 65 F and decreasing in temperature to 45 F for increasing periods, excellent results have been obtained. Of the twenty-two patients we have studied sixteen are completely well and five are improved. The remaining patient (case 4 in the table) did not receive treatment. Patients also can be desensitized to cold by subcutaneous administration of 0.1 mg or less of histamine twice daily for from two to three weeks.

THE LITERATURE

We have been unable to find a review of the relevant literature in English. For the benefit of students of the subject we herewith furnish the results of our review. References to seven or eight articles of which we know, but which we have not been able to obtain for actual reading, are not included.

Urticaria attributable to cold has been recognized since 1866. At that time Bourdon⁸ reported the case

⁸ Bourdon. Note sur l'urticaire intermittente. Bull. et mem. Soc. m d. d'hop. de Paris 3: 259-262, 1866.

of a woman, aged 44 apparently in good health, who suddenly, before breakfast, had a feeling of heat and swelling of the neck and complained of malaise and great anxiety. The involved skin was the site of whitened elevations accompanied by violent pruritus. Syncope developed. Under the influence of poultices to the lower extremities and administration of syrup of ether, the malaise and anxiety diminished while the urticaria and pruritus manifested themselves on the trunk and extremities. However, Bourdon stated that on the application of cold lotions to the affected parts at the request of the patient, the signs and symptoms recurred, including "half" syncope. He hurriedly stopped the refrigerating applications and from that moment the patient's symptoms disappeared. The entire clinical syndrome lasted approximately an hour. It is difficult from this description to know whether or not he was actually describing a case of cold allergy with systemic manifestations. Behier⁹ stated that he had been subject to urticaria induced by cold for a number of years and that if he stayed in cold water for too long a time syncope would result. However, he did not report data on an actual instance of syncope having affected him after bathing in cold water. Blachez¹⁰ in 1872 gave the first classic description of urticaria attributable to cold. He described the case of a woman aged 45, who had swelling of the face, hands, neck and feet following exposure to cold. In addition, on one occasion she noted severe burning pain along the course of the esophagus and in the throat following the swallowing of iced food. When the hands and feet were swollen she had marked difficulty in flex-

Fig 3—Histamine-like systemic reaction in a woman aged 59 produced by immersion of the hand in water at 10°C (50°F) for six minutes. The blood pressure cuff around the arm was inflated to more than systolic blood pressure before the hand was immersed in water and was kept inflated for an additional five and one-half minutes after the hand was taken out of the water. Swelling of the hand did not occur during this period. One and a half minutes after the cuff was released there was a sharp drop in blood pressure and a rise in pulse rate with an unusually severe systemic response.

ing the fingers and could walk only with great effort. The clinical syndrome that he described lasted approximately thirty minutes.

Additional reports of single cases of urticaria attributable to cold with only local manifestations were

published in the next forty years by Münchmeyer,¹¹ Ungar,¹² Schutz,¹³ Ward,¹⁴ Fraser¹⁵ and Hewlett¹⁶. Netter¹⁷ in 1921 and Kleeberg¹⁸ and Wagner¹⁹ in 1922 also reported single cases. In the latter year Widal, Abram and Lerinoyez²⁰ reported the case of a healthy woman aged 37, who had urticaria on the face, neck and hands as well as on the entire body after taking a cold bath; these manifestations were fol-

Fig 4 (same patient as in fig 3)—Histamine-like systemic reaction produced by immersion of hand in water at 96°C (49.3°F) for a period of nine minutes. Determinations of gastric acidity are shown and the usual drop in blood pressure and rise in pulse rate are illustrated.

lowed by general malaise which undoubtedly represented a mild, systemic reaction from undue exposure to cold. Duke in 1924 described the case of a physician, aged 43, who had complained of hives of five months' duration. The patient noticed that exposure of his face to cold wind would cause swelling of the tongue, cheeks, eyelids and ears with associated burning, itching and redness of the skin, excessive lacrimation, itching of the eyes, sneezing and cough. The drinking of cold water caused pain in the mouth, throat, esophagus and stomach. On one occasion, when he had been exposed more than usual to cold he had a severe constitutional reaction which caused total collapse and required epinephrine for relief. No statement was made as to whether or not this followed swimming.

In the next three years, additional cases of local reaction following exposure to cold were reported by Krakauer,²² by Podesta²³ (two cases) and by Freund²⁴ (three cases). Joltrain, Morat and Ley²⁵ in 1927 reported a case in which there was both a local and a systemic reaction. In 1927 one of us²⁶ reported two cases in which local and systemic symptoms of hypersensitivity to cold were exhibited by the patients. The systemic reactions were so striking as to constitute a clinical entity which was first fully described at that time.

One of these two subjects, apparently a healthy man aged 22, had first consulted us in November 1925. At that time he complained of tingling and burning sensations of the body when exposed to cold. These symptoms had been present for three months. His first attack of urticaria had developed after he had been swimming. He felt weak when he came out of the water and fainted on his way to the dressing room. We have not found in the literature an earlier report of syncope following swimming. Report of an additional case with a local reaction was given by Watrin²⁷ in 1927. In the same year Gougerot, Peyre, Moutet and Bourdillon²⁸ reported the case of a man, aged 39, who had both local and systemic manifestations following exposure to cold. Ravaut,²⁹ in discussing this report, stated that he had observed two subjects who had generalized urticaria following exposure to cold. Jadassohn and Schaaf³⁰ in 1928 reported the cases of a brother and sister on whom wheals formed following exposure to cold and in whom the urticaria was chiefly confined to the hands and face. Lehner³¹ in February 1929 reported a case concerning a man, aged 23, who was hypersensitive to cold and collapsed after being in swimming. He had to be rescued from the water. A little later the same year Harris, Lewis and Vaughan⁴ reported the case of a man, aged 64, who had had a definite systemic reaction earlier in life following swimming. Syncope, however, had not occurred. Five months later, in 1929, two of us³² reported four additional cases, the patients were a boy aged 15 years, a woman aged 32, a woman aged 57 and a man aged 30, all of whom had had unusually severe local and systemic reactions after being in swimming. Syncope had resulted in each instance and one of the subjects was unconscious for more than an hour. Another of the four subjects had to be rescued from the water. Additional reports of cases in the same year were made by Perutz, Brugel and Grünfeld³³ (two cases) and Pasteur

Vallery-Radot and Rouques³⁴ (two cases), in one of the latter two cases there was also a systemic reaction.

Reports of single cases, with only local reactions, by Schmidt-Labaume³⁵ and by Haxthausen³⁶ appeared in the literature for 1930. Covisa and Prieto³⁷ reported one case in which there was a local reaction and an additional case in which both local and systemic reactions occurred.

Reports of single cases in which there were local manifestations were recorded in 1931 by Blackford³⁸ and by Pasteur Vallery-Radot and Blamontier³⁹. Bray,⁵ about the same time, gave an unusually interesting report, with experimental data, concerning a boy aged 8 years who had local and systemic reactions. After the hand had been placed in water at a temperature of 45 F for five minutes and then taken out, the usual local reaction of swelling and redness occurred. Five minutes later, some linear wheals appeared, spreading up the arm from the thickened edge toward the axilla, along the lymphatics, which became raised, red, thickened cords. This is the first time that any observer

Fig. 5 (same patient as in fig. 3).—Changes in blood pressure, pulse rate and gastric acidity after the subcutaneous administration of 0.5 mg of histamine without exposure to cold.

reported involvement of the lymphatics in this manner following such an experiment. We observed the same phenomenon in one of our own cases. Bray was able to desensitize his patient by administration of histamine, after which the systemic reaction entirely disappeared and only a slight local reaction occurred following exposure to cold. Subcutaneous injections were given daily, the dose being increased from 0.1 mg of histamine to 0.9 mg by daily increases of 0.05 mg. The 0.9 mg dose was repeated on four consecutive days and the dose of 1 mg on five successive days. The total amount of histamine given was 16.2 mg in twenty-five injections over twenty-seven days. At the completion of this treatment, placing the hand in water at 45 F for five minutes was followed by a mild, local, urticarial reaction of the immersed part, but no general reaction was observed. Forty-five days later, when immersion of the hand was repeated in ice water for five minutes only, a mild local reaction was experienced, even slighter than that previously noted.

In 1932 additional cases in which marked systemic reactions and syncope occurred were reported by Bern-

stein⁴⁰ (two cases), by Thannhauser,⁴¹ by Grassl⁴² (two cases), by Wilder,⁴³ by Urbach⁴⁴ (two cases) and by Klotz⁴⁵. In each instance syncope had followed swimming and three of the nine subjects had to be rescued from the water. In addition, Bernstein Klein⁴⁶ and Eiselberg⁴⁷ each reported two cases and Weiss⁴⁸ one case, in which reactions were only local.

Marquardt⁴⁹ in 1933 reported three cases in which there were only local reactions. Riehl and Resak⁵⁰ also reported one case of local and one of systemic reaction. Zum Busch,⁵¹ Benjamins⁵² (six cases, in five of which there were systemic reactions), Affolter⁵³ and Schlenker⁵⁴ all reported cases in which there were local as well as systemic reactions, in five instances syncope had occurred following swimming. One of the subjects had to be rescued from the water. Another patient collapsed in a physician's office.

Paul¹⁵ in 1934 reported one case in which there were local manifestations. One of us⁶⁰ also reported a case in this year in which local and systemic manifestations occurred. In this case syncope had developed after swimming. Dubbs⁵⁷ and Levine⁵⁸ each reported a case in 1935 in which there were local manifestations. Kobacker and Parkhurst⁵⁹ reported the cases of three sisters in whom hypersensitivity to cold developed following measles. They made spontaneous recovery.

SUMMARY

Of the twenty-two subjects in our series, fourteen had systemic reactions. Eleven of the fourteen subjects who had systemic reactions developed syncope, the syncope of nine of these eleven subjects occurred after swimming and four of the nine had to be rescued from the water. From the literature, we have gathered records of seventy-six cases of hypersensitivity to cold (not including seven of our own cases which have been reported previously). Twenty-nine of these subjects had systemic reactions and eighteen of the twenty-nine developed syncope, the syncope of fifteen of these eighteen subjects appeared after swimming. Four of these fifteen subjects had to be rescued from the water.

All together, this constitutes a series of twenty four cases of syncope following swimming. Eight of these subjects had to be rescued from the water, thus emphasizing our original statement that "Danger lurks at the bathing beach for those who are hypersensitive to cold."

ABSTRACT OF DISCUSSION

DR ISIDORE FINKELEMAN, Chicago. Previous reports on this work were that there is a momentary rise of blood pressure as a result of immersing the hand in very cold water. I am doing some work along this line, immersing the patient's hands in cold water and occasionally immersing the whole body in cold water. What I am interested in is whether these patients mentioned by Dr Horton, who are hypersensitive to cold, have a lowering of blood pressure rather than a rise. I didn't clearly follow his remarks.

DR. CHAUNCEY D. LEAKE, San Francisco. Will the same type of reaction occur in the patients with the administration of acetylcholine? Further, is there any possibility that it may be linked with an enzymatic inhibition? Enzymes are sensitive to temperature changes. It is believed that acetylcholine is constantly being hydrolyzed in the body, so that a very high concentration is not present except under certain conditions. If its enzyme hydrolysis is inhibited, the concentration rises sufficiently to produce an effect. Similarly it may be that an enzyme factor may be involved in the presumed histamine effect.

DR. A. C. TENNEY, Chicago. The use of cold in ascertaining essential hypertension has been used a great deal in a diagnostic way. Is there any hookup between these observations and such cases of hypertension?

DR. MORRIS H. NATHANSON, Minneapolis. I should like to know whether Dr Horton was able to reproduce the typical histamine headache in his experiments. As regards the effects of choline, the systemic action seems to be considerably different from that of histamine. The salivation and lacrimation following a subcutaneous injection of acetylcholine are very marked. The gastric secretion is much less affected. It is probable that choline is more quickly destroyed than histamine. I have applied a tourniquet to an extremity and injected the choline compound below the tourniquet. When the tourniquet was released in about ten minutes the systemic reaction did not follow.

DR. BAYARD T. HORTON, Rochester, Minn. Regarding Dr Leake's question with reference to acetylcholine, I may say that our studies thus far do not indicate that acetylcholine plays any particular role in the production of the syndrome which I have just described. The stimulating influence of acetylcholine on gastric secretion is much less marked than that produced by histamine. Some subjects fail to display any alteration in gastric secretion on the administration of acetylcholine whereas a normal response in gastric secretion invariably follows the administration of histamine. Then too one cannot reproduce the general systemic symptoms in subjects who are hypersensitive to cold by the administration of acetylcholine, whereas patients have been unable to distinguish between the systemic manifestations produced by the subcutaneous injection of histamine and those produced by immersion of the hand in cold water. We have failed to isolate histamine or histamine-like substances from the blood stream at the height of the systemic reaction produced by exposure to cold although we have made repeated attempts to do so. Likewise we have been unable to demonstrate histamine in the blood stream after the administration of known amounts of that substance even when it has been given to the point of producing shock. We cannot therefore definitely say that this clinical syndrome is due to the liberation of histamine from the skin and other tissues following exposure to cold although we can reproduce every single phase of the syndrome, both local and general with the use of known amounts of histamine. This report should not be confused with the cold test for essential hypertension which was recently described by Dr E. A. Hines and the late Dr. George E. Brown. Their test was an outgrowth of this study. For their test the hand is placed in ice water (4 C.) just above the wrist for a period of one minute. Readings of the blood pressure are taken at the end of thirty seconds and again at the end of sixty seconds. The maximal reading obtained while the

hand is in the ice water is taken as the index of the response. The changes in blood pressure occur promptly and are on a reflex vasomotor basis, whereas in our study of subjects hypersensitive to cold an interval of from three to six minutes elapses after the hand is removed from the cold water before a drop in blood pressure occurs. Furthermore, the tourniquet test, which prevents the return of blood from the exposed hand, definitely rules out a reflex basis for the changes in blood pressure and other systemic reactions which we have observed. Changes in blood pressure and systemic manifestations do not occur as long as the tourniquet is in place, however, they do occur promptly and in an exaggerated form when the tourniquet is released.

CHRONIC ENDEMIC DENTAL FLUOROSIS

(MOTTLED ENAMEL)

H TRENDLEY DEAN DDS

Dental Surgeon United States Public Health Service
WASHINGTON, D. C.

The endemic hypoplasia of the permanent teeth known as chronic endemic dental fluorosis, or mottled enamel, is a water borne disease associated with the ingestion of toxic amounts of fluorides in the water used for cooking and drinking during the period of calcification of the affected teeth. The permanent teeth in particular are affected, although in areas of medium to marked severity the signs of mottled enamel are at times observable on certain of the deciduous teeth.

The causative factor of mottled enamel is operative during the period of tooth development. Hence the affected teeth erupt, showing the characteristic markings of the hypoplasia. Normally calcified teeth erupt showing a smooth, glossy, translucent structure, usually of a pale creamy white color. Teeth affected with mottled enamel, on the contrary, erupt showing a dull, chalky white appearance which in many instances later take on a characteristic brown stain, the frequency of brown stain increasing with age. In areas of marked severity, the surface of the teeth may in addition be marked by discrete or even confluent pitting. As the enamel forming organisms, the ameloblasts (gano-blasts), cease functioning at the time of the eruption of a tooth, mottled enamel is a permanent physical disfigurement. For purposes of classification, the various types¹ of the several degrees of severity have been divided into normal, questionable, very mild, mild, moderate, moderately severe, and severe.

References to this disease in the literature are comparatively recent, the first report being that of Eager² in 1901. The extensive investigations of McKay³ published in 1916 pointed unmistakably to mottled enamel being a water borne disease. Final proof of the validity of this hypothesis was furnished by McKay⁴ with the successful consummation of the Oakley (Idaho) experiment. Shortly after the publication of McKay's original report in 1916 the signifi-

cance of this endemic defect of the teeth as a health problem was inferred by Smith,⁵ who late in the same year called the attention of public health workers to the importance of mottled enamel as a hygienic question.

PREVALENCE

The distribution is world wide. In the United States there are about 335 endemic areas distributed among twenty-five states. Eighty-six per cent of these areas are located west of the Mississippi River, the most severely affected state being Texas.

In that portion of West Texas studied, a region about equal in square miles to the state of Pennsylvania, the causative factor of mottled enamel is operative over a vast district. A high percentage of the many thousands of children residing in this region during the period of calcification of the permanent teeth have developed, or are developing, mottled enamel. The ubiquity of the disease there is startling. Of the approximately 335 surveyed or reported endemic areas in the United States, ninety-four, or about 28 per cent, are found in Texas. Other states in which mottled enamel is known to constitute an important public health problem are Colorado, South Dakota and Arizona. East of the Allegheny Mountains a number of small communities located in the Atlantic coastal plain region of Virginia, North Carolina and South Carolina are affected.

Among the foreign countries the Argentine Republic is no doubt the most seriously affected, with about 175 endemic areas reported.⁶ Other countries where endemic areas have been recorded are England,⁷ Italy,⁸ North Africa (Morocco, Tunisia and Algiers),⁹ China¹⁰ and Japan.¹¹ Extensive studies are apparently being carried on at present in the Argentine Republic and North Africa. Other countries in which this problem has been the subject of investigation within the past few years are England, Italy and Japan.

ETIOLOGY

There is strong presumptive evidence that the causative factor of mottled enamel is the presence of toxic amounts of fluorine, present as a fluoride, in the water used for drinking and cooking during the period of calcification of the permanent teeth. The conclusions in 1931 of three independent investigations¹² pointed

to fluorine as the etiologic factor. A carefully controlled experiment¹³ in which municipal water was used from Conway, S. C., an endemic area, demonstrated that changes in the teeth of white rats given a concentrate of the Conway water were similar to those produced by water containing comparable amounts of sodium fluoride. The extensive survey about this time by Boissevain¹⁴ in Colorado added further evidence to support this theory. Further experiments at this laboratory indicated,¹⁵ at least with respect to white rats, that, while fluorine is the chief factor, other conditions possibly influence its action. There was a marked difference in the effect of a given quantity of sodium fluoride, depending on whether it was administered in the water or in the food.

Thorough surveys thus far made, though limited in number, have indicated that when an adequate number¹⁶ of children are examined in a community having the requisites for quantitative evaluation there is an orderly uniformity in the group response to the fluoride concentration of the communal water supply, with

among the adult population of an endemic area is at present undetermined. The work of Boissevain and Drea¹⁷ on human bones, taken in conjunction with the reports of various workers in comparative pathology,¹⁸ is at least suggestive of skeletal involvement. If so, the time factor must be extended to cover adults. Lemon,¹⁹ a pediatrician of Amarillo, Texas, an endemic area, records that "some of these babies have more tendency to bowing of the legs, even in the face of constant antirachitic therapy, thus supporting the theory that the toxic fluorides interfere with bone and dental metabolism."

HISTOPATHOLOGY

The first report on the pathologic histology of this disease was that of Black²⁰ in 1916, who noted that the identifying characteristic was the absence of the cementing, or interprismatic substance, between the outer fourth and the outer third of the enamel rods. Black states that no injury to the enamel rod was observed and that the dentin was normal. In 1923 Williams²¹ confirmed the observations of Black respect-

ing the absence or gross malformations of the interprismatic substance and added that in some instances the defective enamel structure extends to the dento-enamel junction. Black's opinion that the defect in mottled enamel was limited to the substance between the rods was based on examinations under the low and medium powers of the microscope and without the benefit of the silver nitrate staining technique as used by Williams. The latter, using a high resolving power of the 2 mm and 3 mm apochromatic objectives, found that the enamel rods were incompletely calcified. Imperfectly fused granules and small spherical bodies were frequently observed, the larger of these globular masses appearing to be identical with what are known as calcospherites. The histologic picture of mottled enamel disclosed no

essential difference from that of incompletely calcified forming enamel, or enamel showing the early stages of caries. In 1925 Beust²² called attention to the fact that, in addition to the enamel, the dentin was likewise affected, a condition which he termed mottled dentin. Black had stated that the dentin was normal while no reference to this tissue had been made by Williams. The observation of Beust with respect to dentinal disorder has been confirmed by Ainsworth,²³ who reported

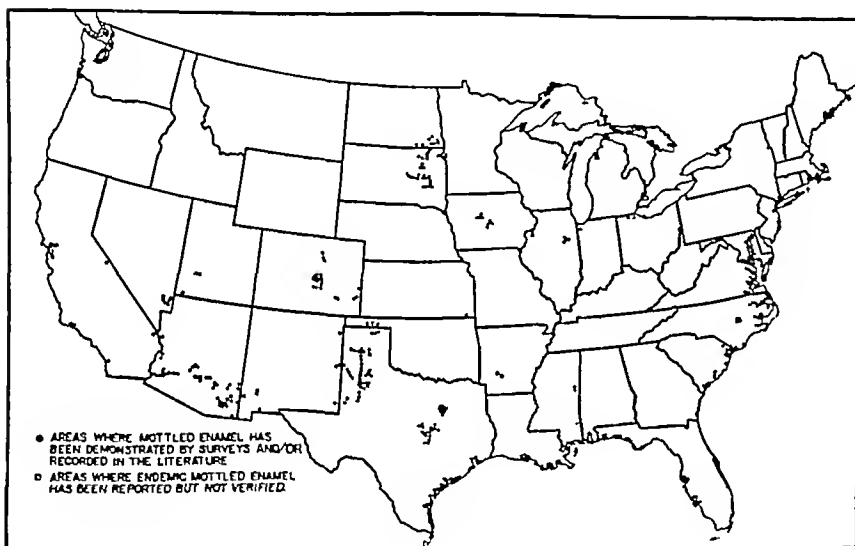

Fig. 1—Geographic distribution of mottled enamel in the United States in April 1936

regard both to the incidence and to the percentage distribution of severity, particularly the latter.

The minimal threshold of toxicity in drinking water has not yet been definitely established, but studies to date would suggest that amounts not exceeding one part per million, expressed in terms of fluorine (F), are of no public health significance.

PEOPLE AND TIME FACTOR

There is apparently no race, color or sex differentiation. In endemic areas—at least with respect to the permanent teeth—only those individuals are affected who have used a water containing toxic amounts of fluorides during the period of calcification of their permanent teeth. Whether or not there are other signs or symptoms of fluorosis as yet unobserved

imperfectly calcified dentin with interglobular spaces such as may be seen in any ordinary case of hypoplasia Ainsworth further notes that the pitting observed macroscopically on the surface of the enamel may be explained as a breaking off of the ends of enamel layers weakened by the loss of the inter-

residing in endemic areas, an observation which I have as yet been unable to confirm Ainsworth²⁴ and Lemmon¹⁰ have also suggested that the deciduous teeth erupt somewhat later than usual

From observations that I made in areas of relatively high fluoride concentration (more than 4 parts per million of fluorine) there is sufficient evidence to suggest that there is an apparent tendency toward a higher incidence of gingivitis

DOMESTIC ANIMALS

The production of an analogous pathologic condition under natural conditions in certain domestic animals has been reported in North Africa,⁹ the United States²⁵ and the Argentine Republic²³ This endemic hypoplasia particularly affects those domestic animals requiring several years for the calcification of their permanent teeth such as the horse the cow and the sheep In North Africa especially, this phase of the problem has been the subject of considerable investigation²⁶

INCIDENCE

The incidence in an endemic area may be high Among those children exposed to waters containing relatively high amounts of toxic fluorides during the first eight years of life, an incidence of from 80 to 90 per cent is not uncommonly observed In some instances it may reach 100 per cent Both the incidence and the percentage distribution of severity of the condition has been found to vary in relation to the fluoride concentration of the water For epidemiologic purposes and subsequent correlation with chemical and other studies, the determination of a community mottled enamel index is advisable These indexes which have previously been described¹⁰ are negative, borderline, slight, medium, rather marked, marked, and very marked

The actual mottled enamel index of a community should not be computed unless there have been no physical changes in the set up of the water supply concomitant with the life period of the group examined For practical purposes, however, an approximate mottled enamel index may be developed if the interruptive variable in the water supply is such that it can be mathematically appraised The group of chil-

(All fluoride determinations were made by senior chemist Elias Elyoye, United States Public Health Service and with the exception of those for Post Texas have been reported in two previous articles [Dean and Elyoye footnotes 16 and 28]. For information concerning the history of each water supply seasonal variations or chemical methodology the reader is referred to these papers.)

prismatic substance. He adds that the layers of enamel formed between the striae of Retzius are broken off almost at right angles to the striae so that they show on the floor of the pits as a series of angular outcrops, giving in one section a definitely serrated appearance not unlike the pits in other forms of hypoplastic teeth. Erasquin²³ reports that the permeability of mottled enamel is comparable to that of immature normal (unruptured) enamel and enamel affected by caries. The permeable zone that characterizes mottled enamel is always the most external, its intensity diminishes from the outside inward.

RELATION TO OTHER ORAL PATHOLOGIC CHANGES

In spite of its defective structure, mottled enamel teeth according to McKay,²⁴ exhibit no greater liability to caries than do normally calcified teeth; an inference apparently substantiated by the studies of Masaki,¹¹ Ainsworth²⁴ and Erasquin.⁶ Masaki¹¹ and Ainsworth²⁴ have likewise called attention to an apparent delay in the eruption of permanent teeth of children

Fig. 3—Graphic summary of data in figure 2 showing quantitative relation of fluoride (F) concentration to clinical effect.

dren must consist of at least twenty-five individuals 9 years of age or older, whose time of risk of exposure has been constant, meaning that the children were born in the community, had lived there all their lives (short breaks in continuity totaling less than thirty days in any calendar year excepted) and had always used the

municipal or communal water supply both for cooking and for drinking. In cases in which the examination of the first twenty-five children discloses an incidence of less than 75 per cent, it has been found desirable, if not necessary, to increase the number in the group to fifty or more in order to compensate for fluctuations in sampling and their possible effect on the computation of the mottled enamel index.

The group examined should preferably consist of 9, 10, 11 and 12 year old children. Clinical observations limited to 9 year old children in areas in which the fluoride concentration of the water is less than 3 parts per million have a tendency to give a slightly lower incidence²⁷ than if the survey had embraced the four age groups mentioned.

QUANTITATIVE RELATION OF CONCENTRATION TO ACTION

In surveys made of cities having the requisites for quantitative evaluation²⁸ and even where these requisites are closely approximate, there is a definite quantitative relation between the fluoride concentration and the clinical effect. Although a prognosis with respect to any one individual is obviously unwarranted, it is felt that a prognosis relative to the group response to waters of varying fluoride concentration may be tentatively made at this time. From the continuous use of water containing about 1 part per million, it is probable that the very mildest forms of mottled enamel may develop in about 10 per cent of the group. In waters containing 17 or 18 parts per million, the incidence may be expected to rise to 40 or 50 per cent, although the percentage distribution of severity would be largely of the "very mild" and "mild" types. At 25 parts per million an incidence of about 75 to 80 per cent might be expected, with possibly 20 to 25 per cent of all cases falling into the "moderate" or a severer type. A scattering few may show the "moderately severe" type.

At 4 parts per million the incidence is, in general, in the neighborhood of 90 per cent, and as a rule 35 per cent or more of the children are generally classified as "moderate" or worse. In concentrations of 6 parts per million or higher an incidence of 100 per

cent is not unusual. In other words, we are dealing with a low grade chronic fluorine poisoning of children and the action on the group roughly follows the general pharmacologic observations of Shackell,²⁹ respecting the quantitative relation of concentration to effect.

PREVENTION

In the light of present knowledge, this disease is readily preventable. The logical approach to the solution of this problem is, of course, avoiding the use of water containing fluorides in excess of the permissible limit. In some instances this can be accomplished by simply changing to a readily available source in the same neighborhood that is free of toxic amounts of fluorides. Examples of this are the towns of Oakley, Idaho, previously referred to,⁴ and Bauxite, Ark.,³⁰ which abandoned its deep wells and turned to the nearby Saline River as the source of its water supply.

Where such changes are not entirely feasible, it may be possible in some cases, especially where the water contains less than 2 parts per million, to dilute an otherwise satisfactory water supply with another water that will bring the final fluoride content down within the permissible limits. And while these changes are being made, it is well to bear in mind that the only portion of the population known to need protection is the group of children between birth and 8 years of age, inclusive. For this group it is possible in many cases to provide distilled or cistern water for drinking and cooking purposes during the susceptible period, the first eight years of life.

Finally, in those areas in which a satisfactory water is not available, the ultimate solution in such cases would have to depend on a suitable method, economically feasible, of treating the existing water supply by chemical means for the removal of toxic amounts of fluorides.

National Institute of Health

ABSTRACT OF DISCUSSION

DR. CARL F. JORDAN, Des Moines, Iowa. In 1933, after completing a nation-wide survey, Dr. Dean reported 125 localities in this country representing endemic areas giving rise to mottled enamel. He now reports a total of 335 endemic areas with distribution in twenty-five states. In 1932 a dentist, Carl T. Ostrem, was first to report mottled enamel in Iowa affecting school children at Ankeny, near Des Moines. A state wide survey was begun in 1933 by the Iowa State Department of Health. To date fourteen areas of mottled teeth have been discovered. Iowa is fortunate in that the endemic areas listed at this time affect no cities with a population over 2,000. The chief method of prevention of mottled enamel lies in securing a water supply free from fluorine. Changing the water supply offers difficulties in a community using deep well water containing fluorine where there is no convenient access to another water supply free from this element. On the other hand if the change can readily be made, failure to do so should constitute negligence on the part of officials. Bauxite, Ark., and Oakley, Idaho are striking examples of towns which have changed their water supplies and where children are now free from the mottled enamel defect. Further steps are needed to overcome the apathy of officials in certain communities toward this unfortunate dental defect. First hand observation of the moderately severe form of mottling with the associated brown

27 Two related factors are probably the cause of this somewhat lower incidence in a survey limited to the 9 year old group. First in endemic areas of relatively low fluoride concentration (less than 2 parts per million) there is in a fair proportion of the children of comparable and constant residence and water history a tendency to show the milder forms of mottled enamel only on the bicuspid and second molars, a group of teeth which according to Kronfeld (*Development and Calcification of the Human Deciduous and Permanent Dentition*, The Bur, March 1935) begin their calcification at a somewhat later date than the incisor first molar group. This manifestation of mild dental fluorosis in teeth calcified at a later date is suggestive of a cumulative action of fluorine. Second based on an analysis of the 162 schedules of the Colorado Springs-Pueblo survey¹¹ only about 1 per cent of the permanent second molars, 7.2 per cent of the second bicuspid and 20.5 per cent of the first bicuspid were erupted in the 9 year age group. It follows therefore that certain 9 year old children are necessarily classified as normal on the basis of the absence of mottled enamel on the incisor first molar group when, if the same individual were examined a year or two later, it might show objective signs of mottled enamel on the bicuspid second molar group and be so classified. Adjusting for this minus variation for instance in a survey of a community like Colorado Springs where the mean annual fluoride content of the city water is 2.5 parts per million of fluorine, an examination of 9, 10, 11 and 12 year old children would probably result in raising the incidence from 67 per cent for the 9 year old group exclusively to a general rate of about 75 to 80 per cent if the sample consisted of the four age groups mentioned. Because the percentage distribution of severity in the 9 year group examined in this city is so near that of the next higher index, it is probable that, in this instance, the community mottled enamel index would be raised from slight to "medium." In areas where the fluoride content of the water is between 1.5 and 2 parts per million it is unlikely that this difference would have any effect other than a slight increase in the incidence. In areas of relatively high concentrations the effects of this variation would of course be negligible.

stains, in children whose teeth are otherwise perfect in form and arrangement, will do much to dispel indifference. Dr Dean referred to the recent work of J R Lemmon, a pediatrician in Texas, who reported defective development of the long bones in babies whose diet includes water with fluorides in toxic amount. Further clinical studies might well be carried out by physicians to demonstrate harmful effects apart from the enamel dystrophy. Such work would supplement noteworthy contributions that have already been made by Dr Dean and others and would promote measures designed to prevent mottled enamel of the teeth.

DR. STANLEY H OSBORN, Hartford, Conn. I should like to ask Dr Dean if there are any other conditions in the body that this affects, such as endocrine disorders or difficulties.

DR. L D BRISTOL, New York. I should like to ask whether there is any correlation between mottling of the enamel and what might be called mottling of the skin as a result of this type of water. The tale is frequently heard that these so-called liver spots on the skin are nothing but a mottling due to certain types of alkaline water.

DR. H T DEAN, Washington, D C. There are several articles in the literature suggesting a possible relation between fluorine and the endocrines. First there is the report of Goldemberg, who attempted to show a relationship between fluorine and endemic goiter; this work, of course, is not generally accepted. With respect, however, to the parathyroids, several investigations are of interest. In 1911 Erdheim reported the effect of parathyroidectomy on rats. The structural defects in the incisor teeth of the parathyroidectomized animals were apparently similar to the defects now associated with experimental fluorosis. With this as a basis, a group at the University of Wisconsin a few years ago attempted to determine whether there were demonstrable changes in the parathyroids of rats affected with fluorosis. The experimental group was fed a relatively high fluoride concentration but the gross and histopathologic examination failed to show any consistent significant changes. There is a considerable literature suggesting possible skeletal involvement. Cristiani working with guinea pigs found that the fragility of the bones was increased about 20 per cent in the fluorized animals. Suto has recently reported in the *Archives of Pathology* definite osseous changes, an osteosclerosis, in rats fed fluorides over a period of time. The experiments which I have just cited were of course on experimental animals. The work, however, of Boissevain and Drea at Colorado Springs is of particular interest because they were dealing with human material. These workers found that bones of residents of Colorado Springs or Cripple Creek contain about six times as much fluorine as that found in the 'control' bones, which were from New York City and Washington, D C. The biochemical observations in this study were confirmed by spectroscopic examination. Regarding the question asked by Dr Bristol, there are two references in the literature that may be pertinent. Black in 1916 stated that he thought the defect was more pronounced in children predisposed to freckling. Lemmon in a recent article in the *Texas State Journal of Medicine* states that mottled enamel occurs more frequently in blonds and 'redheads.' However, I know of no definite correlation on this point. The suggestion of Dr Jordan is well taken, namely that the possibilities of untoward effects of fluorine on the skeletal system of inhabitants of endemic areas should be thoroughly explored. An excerpt from a paper by Velu published in the *Bulletin* of the Academy of Medicine at Paris a few years ago is particularly relevant. Referring to 'le darminous,' the name by which this disease is known in North Africa, Velu referred to the condition as 'the fluorine sign of the inapparent intoxication.' The question of legal liability has arisen in connection with common water supplies containing toxic amounts of fluorides. There is a report that in one endemic area two damage suits have been filed against the municipality. It is a new phase of the problem and in several states health officers, sanitary engineers and city officials are giving this new development serious consideration.

Vitamin C in Staple Foods—Fruits, vegetables and milk are the practically important sources of vitamin C among our staple foods.—Sherman, H C. Food and Health. New York, Macmillan Company, 1934.

THE THERAPEUTIC USE OF HELIUM

ALVAN L BARACH, M D
NEW YORK

The basis for the proposal of helium as a gas for therapeutic use in certain types of dyspnea occurring in clinical disease depends wholly on its decreased specific gravity in relation to nitrogen¹. Since the weight of a comparable volume of nitrogen is seven times greater than that of helium, a mixture of 21 per cent oxygen and 79 per cent helium may be substituted for 21 per cent oxygen and 79 per cent nitrogen, namely air, thus providing a respirable gas mixture which has one-third the density of air. During quiet breathing the influence of such a decrease in weight is practically negligible. The physical law which provides that the force required to move an object is proportional to the weight of the object does not, however, indicate that one-third the effort employed in breathing air would suffice for the inhalation of the helium-oxygen mixture. The pressure maintained in the tubal system of the respiratory tract in quiet breathing is so small that no significant change in intratracheal or intrapleural pressure was observed in animals as a result of the substitution of the lighter gas mixture. When inspiration has once been initiated, the passage into the lungs of either air or a helium-oxygen mixture is consciously almost effortless, expiration is completely so.

However, when there is an obstruction in any part of the respiratory tubal system, an increased negative pressure within the chest becomes necessary for the inward movement of air past the obstruction, and there exists in the passageway between the lung and the site of obstruction a marked increase in pressure of the atmosphere being transported. During violent dyspnea without obstruction, in which large volumes of air are moved in and out of the lungs at a high velocity, the smaller elements in the respiratory tubal system act as a relative constriction, and here too the air is under increased pressure. The function of a helium-oxygen mixture may now be explained by the physical formula. The velocity of movement of a gas through small orifices is proportional to the square root of the density of the gas. The pressure required for the movement of an 80 per cent helium-20 per cent oxygen mixture would be almost one-half that required for air. In human subjects who breathed through narrow orifices, an actual reduction as high as 50 per cent was found in the pressure of a helium-oxygen atmosphere as compared to air². Since pure oxygen is slightly heavier than air, approximately the same reduction in physical force takes place when the helium-oxygen mixture is substituted for 100 per cent oxygen. Furthermore, in experimental respiratory obstruction in animals and in a patient in severe asthma, a reduction in intrapleural negative pressure was found when the helium-oxygen

mixture was substituted for air.³ This saving in respiratory effort has been made use of in patients with severe asthma or obstructive lesions in the larynx, trachea and bronchi.⁴ In this report the principles and clinical application of the therapeutic use of helium in a larger series of cases will be described.

HISTORICAL

Helium was isolated from the mineral cleavite by Ramsay⁵ in 1895. It was later found to be a constituent of the air to the extent of one part in 200,000. It is now obtained from certain natural gases and is used in dirigibles because of its buoyancy, having replaced hydrogen because it is free from explosive possibilities. In 1923 Cooke⁶ called attention to the fact that helium had a coefficient of solubility half that of nitrogen and a diffusibility twice as great. Sayers and Yant⁷ in 1926 showed that animals could be decompressed from ten atmospheres of helium-oxygen mixture in one-third the time necessary for a nitrogen-oxygen mixture. Elihu Thompson⁸ in 1927 called attention to correspondence with the U. S. Bureau of Mines in which he suggested the use of helium for divers in 1919.

Fig. 1—Helium pressure rebreathing apparatus

Hershey⁹ reported that animals could not survive in atmospheres in which the rare gases were excluded. However, I¹⁰ carefully tested this hypothesis and showed that animals were apparently uninfluenced in atmospheres in which all the rare gases were excluded for as long as forty-two days. Furthermore, animals (mice) were kept in completely sealed chambers in which there was 21 per cent oxygen and 79 per cent helium for periods as long as two months without obvious change in their general condition. These investigations confirmed in my mind previous evidence of the biologic inertness of the rare gases and helium specifically, the conception of helium as a vehicle for oxygen then took place, based on its physical property of possessing the lowest specific gravity of any of the elements except hydrogen, the highly explosive nature of which forbade its clinical use.

METHODS

The administration of helium presented difficulties not encountered in the therapeutic use of oxygen. In order to obtain satisfactory results it was found highly necessary that nitrogen should be rigidly excluded because of the fact that a leakage of air into the apparatus markedly increased the weight of the mixture and thereby interfered with the specific function of helium. Furthermore, it is important that helium be not hazardedly administered lest an excessive concentration of helium inadvertently result in asphyxia. Since my first clinical communication,⁴ mixtures of from 20 to 25 per cent oxygen with from 75 to 80 per cent helium have been made in a single tank which protects against an undue lowering of the oxygen concentration, provided an adequate flow of the combined gas is continuously administered.

Two general methods have been developed, which are subject to various modifications. For relatively short periods of administration, such as from one-half hour to three hours, a closed circuit rebreathing apparatus has been used with a mouthpiece or a mask. This has been found practicable in adult patients with asthma. The mouthpiece is the same as that used in basal metabolism apparatus; a nose clip is required to exclude air from the nose. The mask is very light and is kept in place by two elastic straps around the head. The closed circuit apparatus contains a motor blower unit which has been specially reconditioned to make it leak tight, one-inch inlet and outlet tubing which connects with a Douglas (or other rebreathing bag) and a soda lime canister. Inserted in the exhalation tubing is a two-way valve which may allow a flow through it or be turned so that the expired air passes into the atmosphere. There is a variable orifice steam valve and a water manometer distal to it, also introduced in the exhalation tubing. The steam valve may be turned so as to produce a resistance in the circuit and thereby increase the pressure in the system, the degree of which is read by a manometer distal to it.

When treatment is begun the rebreathing bag is filled from the tank containing the combined mixture (from 20 to 25 per cent oxygen, the remainder helium). The first filling is washed out by turning to the atmosphere the two-way valve on the exhalation side of the circuit. When the bag has again been filled with the desired mixture the patient is attached to the apparatus through either a mouthpiece or a mask, and the first eight or ten breaths are allowed to be exhaled into the atmosphere through the two-way valve in order that the nitrogen in the lungs may not dilute the helium-oxygen atmosphere. During this period it is desirable to continue to let the mixture run into the apparatus at a rate of approximately 15 liters per minute, in order to maintain a positive pressure until the motor blower unit has been turned on. After the patient's lungs have thus been washed out the two-way valve is turned into the circuit and the motor blower unit turned on. The steam valve is adjusted so that a pressure of 1 or 2 cm. of water is recorded. The gage on the helium-oxygen tank is then lowered to 4 liters per minute. (An oxygen gage can be used but would have to be recalibrated since a higher flow of the helium-oxygen mixture would be admitted at a given reading, a flow gage, a rota-regulator or a calibrated water bottle could be used.) It would be possible after the mixture has been obtained in the rebreathing bag and the patient connected to the apparatus simply to add the oxygen consumption of the patient, entirely reusing the helium.

and making frequent tests of the oxygen concentration in the circuit. However in actual practice it has been found both more convenient and more effective to deliver from 4 to 5 liters of the oxygen-helium mixture continuously during the treatment which accomplishes a partial reusing of helium insures a constant supply of oxygen and tends to maintain the proper helium concentration which inadvertent leaks might otherwise impair. If 4 liters per minute of 25 per cent oxygen and 75 per cent helium is administered to an adult patient his own oxygen consumption will usually lower the concentration in the mixture to between 22 and 23 per cent, the relatively smaller oxygen consumption in infants will but slightly lower the oxygen concentration of the mixture admitted. When the treatment is about to be terminated the valve at the mouthpiece is turned toward air before the patient is disconnected in order not to suck air into the apparatus.

A basal metabolism apparatus could be adapted for helium administration the excess helium-oxygen gas being allowed to bubble out of the water in the spirometer. However a positive pressure is necessary in this method even if it is only from 0.5 to 4 cm. in order that the patient may not be compelled to inhale against the resistance in the circuit. This may be done by inserting a motor blower unit of sufficient capacity or by putting a weight on the spirometer bell. A water manometer may be led from the exhalation side of the circuit and fastened by adhesive plaster to the spirometer.¹¹

The oxygen tent has been employed with certain modifications although maintaining strictly hygienic atmospheric conditions previously described.¹² Helium-proof fabric is used. The motor blower unit is especially reconditioned so that no leaks occur. For infants a tent has been used in which the entire body is enclosed. For adults it is more practicable simply to enclose the head and to make a closure at the neck. The Benedict¹³ helmet respiration apparatus may be used for this purpose or any variety of hood that takes in only the head and neck. Even for infants this type of apparatus seems now preferable to the body tent. When the patient is placed in the tent pure oxygen is admitted at high speed from a needle valve until a test of over 98 per cent oxygen is obtained in the enclosed atmosphere. The tank containing the mixture of 25 per cent oxygen and 75 per cent helium is then turned on at a flow of from 20 to 30 liters per minute until a concentration of 25 per cent oxygen is obtained in the tent. For infants from 2 to 3 liters a minute of the mixture is then admitted for adults from 4 to 6 liters

TREATMENT OF ASTHMA

In the previous clinical communication³ inhalation of helium with oxygen was found beneficial for (1) the patient in status asthmaticus in whom severe asthma became continuous and in whom there was complete refractoriness to epinephrine and all other measures, (2) for cases of severe asthma with partial refractoriness to epinephrine in which epinephrine must be employed five or more times daily to keep the patient

in even moderate comfort. These two groups merge into each other being characterized by the loss of sensitivity to epinephrine. In severe asthma it is a common clinical experience to observe that the patient requires more and more epinephrine to control his asthma and that with the use of increasing amounts of epinephrine a refractory state develops in which only temporary and incomplete bronchiolar dilatation results from its use. Maytum Prickman and Boothby¹⁴ confirmed our results in status asthmaticus, reporting three cases that were promptly relieved, both objectively and subjectively by the inhalation of helium with oxygen after all other measures had been tried and found unavailing. In their opinion these patients looked as if a fatal outcome might otherwise have taken place. In five patients of the present group of eighteen the severity of the asthmatic state was such as to lend weight to the fear that death might momentarily occur.

The mechanism of improvement of status asthmaticus is based on the decreased respiratory effort required for pulmonary ventilation when a helium-oxygen mixture is breathed. Within a few minutes some degree of relief is obtained, although it may be a matter of from two to eight hours before the bronchial spasm is relieved. It appears to be a clinical fact that the early period of relief obtained by the respiratory system as a whole of itself initiates bronchial dilatation. After improvement has become manifest through the inhalation of helium with oxygen the patient promptly recovers some degree of sensitiveness to epinephrine. In some instances even after relatively short periods of administration, such as from two to five hours, the patient becomes completely sensitive to epinephrine and requires no further helium treatment. In other cases periodic inhalations are necessary for from two to five days before complete restoration of epinephrine sensitivity is produced.

In patients who have not progressed to a condition as severe as status asthmaticus but who suffer more or less continued wheezing throughout the day or night with frequent acute paroxysms, the inhalation of helium-oxygen mixtures initiates a variable degree of relief depending on the severity of the bronchial constriction. This may be roughly estimated as between 80 and 100 per cent for what might be termed chronic wheezing and between 50 and 80 per cent for more severe bronchial spasm. In these patients the administration of helium with oxygen through a mask or mouthpiece rebreathing apparatus is employed for most of the time during the day when more or less continuous asthma is present. In some patients sufficient relief will be obtained by breathing the gas under atmospheric pressure, in most a slight positive pressure such as between 0.5 and 4.0 cm. of water pressure, is desirable. The increased pressure facilitates the entrance of the gas into the lungs and thus decreases the negative pressure existing within the chest. We have shown in one patient with asthma a decrease of from -11 to -7 cm. intrapleural negative pressure induced by the inhalation of 20 per cent oxygen and 80 per cent helium under 5 cm. positive pressure.¹⁵

In animals breathing through a narrowed orifice, the decrease of the negative intrapleural pressure, breathing a helium-oxygen mixture under positive pressure, has been graphically recorded (fig. 2). As seen in this record a decrease from minus 12 cm. of water to

¹¹ The rebreathing apparatus with mask and mouthpiece may be obtained from the Oxygen Therapy Service Company, New York. Other manufacturers of equipment used are the Mine Rescue Appliance Company, Pittsburgh which makes the masks and the densimeter, Warren E. Collins, Boston who manufactures the Benedict Helmet Respiration Apparatus, the Forrester Company, New York which calibrates water bottles for separate introduction of helium and oxygen, John Emerson, Cambridge, Mass. who makes an infant tent.

minus 7.9 cm occurred during inspiration, and from minus 3.4 cm to minus 0.9 cm in expiration. The presence of continued increased negative pressure within the chest causes an accumulation of blood within the lungs, promotes exudation of serum into the alveolar spaces and retards the filling of the left side of the heart. In animals, edema of the lungs has been produced by subjecting the animal to respiration against a negative pressure of from 3 to 4 cm of water, whereas breathing against a positive pressure of similar degree does not cause these pulmonary changes.¹⁶ These results are comparable to those of Moore and Binger,¹⁷ who reported pulmonary congestion and edema in animals that inspired through a narrow orifice but found no such changes in animals that expired against a resistance. The lungs of dogs in my experiments inhaling either against resistance or against a negative pressure showed not only massive pulmonary congestion and edema but also areas of emphysema. The production of obstructive emphysema, therefore, seems to me to be more related to the effect of a high

Fig 2.—Intrapleural pressure and tidal air in dog breathing through three-sixteenths inch orifice.

1 Air at atmospheric pressure. 2 Air at 5.5 cm of water pressure.

The effect of positive pressure is to reduce the negative pressure within the chest during inspiration and expiration and also the total range of pressure.

intranegative pressure within the chest rather than to any backward distending pressure on the alveolar walls, a view also supported by Prinzmetal.¹⁸

In patients suffering from status asthmaticus, I have observed that the volume of the pulse either is greatly diminished or disappears at the end of inspiration, even in patients with moderately severe asthma the systolic blood pressure drops precipitately at the end of inspiration. I have thought this was due to incomplete filling of the left heart because of the high negative or suction pressure existing within the chest. In one patient in a severe asthmatic state I found an intrapleural negative pressure of minus 20 cm of water. High readings have also been reported by Prinzmetal¹⁸ and others. The physiologic advantage of the administration of helium with oxygen may in part be explained by its effect in lowering the intrapleural negative pressure. By adding a positive pressure in the apparatus, a still further lowering of the negative chest pressure is obtained.

There is, however, a further factor to be considered, namely, that an excessive positive pressure within the chest also decreases the filling of the left side of the heart, with a parallel fall in the systolic blood pressure. Pressures between 5 and 10 cm of water have therefore been given for short periods such as one half hour, and the volume of the pulse and the blood pressure observed during its administration. If the pulse volume is noticeably decreased or the systolic blood pressure falls more than 20 mm of mercury a smaller positive pressure is employed, such as from 1 to 3 cm of water. The higher pressures have been used in patients with tremendous dyspnea, whose state suggested high intrapleural negative pressures, and the lower pressures in the exhausted comatose patient who presented a picture of imminent respiratory failure, in whom high negative pressures within the chest could be assumed to be absent because of the shallow respiration. Conscious patients vary in their subjective response to increased pressure. They are aware of the increased ease of inspiration and the increased muscular effort during expiration. In some, preference is expressed for increased pressure, for example, from 1 to 5 cm, in others, minimal pressures of from 0.5 to 1 cm are found more agreeable.

The history of the following case illustrates the use of helium in the two groups that have been discussed, namely, the state of more or less chronic wheezing, in which the bronchodilating effect of epinephrine was slight and temporary, and the acute severe condition of status asthmaticus in which the patient was comatose, pulseless and gravely ill, with complete refractoriness to epinephrine.

A woman, aged 54, had suffered intermittently from asthma for twenty years. Her allergic work-ups had always been negative. The relation of her asthma to infection had been suspected but never proved. For two months before she entered the hospital she had had more or less continuous wheezing at home with acute paroxysms as well. Epinephrine gave but slight transient relief. She had been in an oxygen tent for two weeks and had morphine intermittently. Her pulse became steadily faster and ran at an average rate of 140, at times 150. She was brought to the hospital in an ambulance. At the time of admission she was seen to be exhausted, dyspneic, orthopneic and cyanotic with sibilant rales heard throughout the lungs. She obtained complete subjective relief with a disappearance of all rales during the inhalation of helium 80 per cent, oxygen 20 per cent, with from 0.5 to 3 cm. of water pressure. She was treated for periods of one half to one hour at a time. During the intervals between treatment in the first two days the wheezing returned as soon as she was disconnected from the apparatus. On the second day she had an acute paroxysm, which was treated with 1 cc. of epinephrine. The attack was relieved but wheezing persisted afterward. At the end of five days she was free from all chronic wheezing. The onset of a mild paroxysm was controlled by 0.5 cc of epinephrine and two days later by 50 mg of ephedrine. Three weeks later, when the patient was getting up and about attacks of asthma recurred, for which the patient took epinephrine. It is noteworthy that she preferred epinephrine when it was effective, to helium, as the relief secured in an acute paroxysm by the inhalation of helium is at best only partial and does not do away with the spasm. Inhalations of helium were not therefore recommended since the patient responded to epinephrine. Formerly when the patient's respiratory reserve had become exhausted by continuous asthma the special function of helium was applicable.

In the course of the subsequent work up of the patient during the period when she had been taking from 2 to 3 cc of epinephrine daily an intracutaneous skin test of taphelococcus vaccine was made. She showed within ten minutes a reddened area about the size of a quarter (24 mm.) at the site of the test. On the following day a cellulitis of the forearm extending to the lower third of the arm was present.

This subsided two days later, during the night the patient went into status asthmaticus, was treated by repeated doses of epinephrine and morphine and in the morning was unconscious, unable to be aroused, breathing in shallow but labored fashion, with the pulse almost imperceptible. She was treated with inhalations of 20 per cent oxygen and 80 per cent helium with a mask and mouthpiece at from 1 to 2 cm of pressure, alpha-lobeline, 25 mg, was given to counteract the effect of morphine, 75 cc. of 50 per cent dextrose was given intravenously to increase the pulse (and circulation) volume, and 0.8 Gm of caffeine with sodium benzoate. At the end of two and a half hours the patient was free from asthma except for a slight wheeze, she was conscious, and the pulse was of good quality. In patients with status asthmaticus, morphine is at times a dangerous drug, as the effort to breathe against the severe bronchial spasm may be diminished without at the same time altering the degree of bronchiolar constriction thereby promoting a dangerous degree of asphyxia. In this instance the patient regained her sensitiveness to epinephrine and to ephedrine in two days and required helium on only one day subsequently, when a continuous wheeze was present. She was subsequently given high dilutions of staphylococcus vaccine and a mixed vaccine and discharged from the hospital with only slight wheezing at night, which was controlled with ephedrine. Follow up five months later has shown steady improvement.

Five of the eighteen patients at one or more of their admissions to the hospital presented a picture of status asthmaticus of such severity as to suggest a fatal outcome. They had become completely unresponsive to epinephrine and to all other measures, cardiac and respiratory failure appeared imminent when treatment was begun. In each case objective improvement followed inhalation of the helium-oxygen mixture, either immediately or within half an hour after beginning of treatment, increasing progressively until epinephrine sensitivity was completely restored in a period which varied between two to five hours and two to five days. One of the patients who had appeared moribund as a result of prolonged asthma prior to admission regained epinephrine sensitivity after one day of treatment, after discharge from the hospital severe asthmatic seizures returned, and one year later he died during a spell of continuous asthma. From what records we were able to obtain, he took epinephrine in large doses for twelve days with progressively diminishing relief. Three other deaths were reported to me in patients who went into status asthmaticus during the same year. Although in a given instance it may be impossible to state that a fatal outcome would necessarily have taken place, the clinical picture warranted such an impression, as it did in the three cases described by Maytum, Prickman and Boothby.¹⁴ In ten other cases in which almost complete refractoriness to epinephrine was present coincident with preexisting prolonged more or less continuous asthma, inhalations of helium with oxygen were followed by subjective and objective evidence of improvement with restoration of epinephrine sensitivity in from one to five days of treatment. In three cases epinephrine refractoriness did not disappear, although the failure to obtain a good result in these instances appeared to be in large part traceable to lack of cooperation on the part of the patients. The length of improvement following helium and oxygen treatment is extremely variable, in some cases severe asthma recurred in from two to four weeks, whereas in others no return of severe symptoms has taken place in from six months to two years.

The search for an etiologic factor must necessarily be a continuous project in many of these very severe cases. The function of helium is viewed as a method

of restoring epinephrine sensitivity when it has been lost and not as a substitute for epinephrine when it is effective.

OBSTRUCTIVE CONDITIONS OF THE TRACHEA, LARYNX AND BRONCHI

In a previous clinical communication³ the relief of obstructive dyspnea in patients with constriction of the trachea or larynx was reported. The results in twenty-one consecutive cases will be summarized.²⁰ The principles already discussed apply in the main, with certain modifications, to obstructive conditions in the upper air passages. Deflation of the smaller bronchial tubes occurs in the asthma patient in expiration, owing to the termination of the inflating effect of the negative pressure within the chest and also in some cases to a positive compressing expiratory force which locks air in the alveoli. In the respiratory tubes outside the chest this effect is absent and furthermore the cartilaginous rings of themselves maintain the integrity of the lumen. In this circumstance may be found the explanation of the relatively prolonged expiration in asthma patients as compared to patients with laryngeal or tracheal obstruction. In the former an attempt to hurry the outflow of air by forcible expiration might collapse the delicate bronchiolar structures and thereby increase the difficulty, expiration, therefore, is generally observed as a more passive, prolonged process in asthma than in obstruction in the upper air passages, where no such dilemma exists. For that reason positive pressure was thought more applicable to asthma than to lesions outside the chest.

The clinical indication for the use of helium in this group is mainly to be found in children in whom inflammatory swelling of the larynx and trachea, due to infection, foreign body or instrumentation, is frequent, although similar conditions occur in adults. Tracheotomy in infants, particularly with previous infection, is so likely to lead to bronchopneumonia that we have attempted to secure through the inhalation of a helium-oxygen mixture sufficient relief from dyspnea and rest to the respiratory musculature as to obviate the need for surgery. Even in adults in whom transient laryngeal edema occurred as the result of x-ray therapy of a carcinomatous lesion or of instrumentation, helium-oxygen inhalation has been tried first, with the cooperation of the laryngologic staff.

Of twenty-one patients treated, five must be excluded either because they were moribund or because helium had to be withdrawn prematurely. There were sixteen remaining patients in whom an opportunity for clinical judgment was present by the pediatrician, the laryngologist and myself.²¹ There were three cases in which the degree of obstruction was such as to prevent adequate relief from the inhalation of helium. Through the use of helium mixed with a variable proportion of oxygen, it should be possible to compensate for approximately a 50 per cent constriction in the lumen of the tubal respiratory system, but it is obvious that obstruction may proceed to a point which will nullify the function of the gas. In eight cases the administration of helium with oxygen was temporarily helpful, at times for as long as eight days, but eventually the progress of the lesion necessitated tracheotomy. Four of these patients recovered and four died. In none of the cases

²⁰ A more detailed report including the interrelation between inhalational therapy and laryngology will be published separately by Kernan and myself.

²¹ The author is indebted to Dr. Rnstin McIntosh, director of the Babies Hospital in the Columbia Medical Center for his cooperation in making this material available.

was there any reason to believe that earlier tracheotomy would have improved the prognosis, whereas the reverse was conceivably true, that a further trial of helium therapy might have been preferable to tracheotomy. The remaining five patients were relieved of the major portion of their dyspnea and recovered without tracheotomy, with an ultimate resolution of the inflammatory swelling causative of the obstruction. It might be mentioned that retraction signs, either above or below the sternum with intercostal retraction, were present in all patients treated.

The function of helium in this group is to provide relief to obstructive dyspnea arising from inflammatory swelling and in that way avert tracheotomy. The laryngologist, however, cannot be dispensed with, as his attendance is necessary during the process of treatment as well as in the eventuality that the degree of relief is insufficient. Even when relief is only partial and retraction signs persist after inauguration of helium therapy, a conservative attitude toward tracheotomy is warranted, for in some instances a slight decrease in the edema increases markedly the effectiveness of helium and the child may be spared a surgical procedure which might itself produce complications.

EMPHYSEMA, BRONCHIECTASIS, PULMONARY FIBROSIS

The clinical illnesses emphysema, bronchiectasis and pulmonary fibrosis, so interrelated anatomically and etiologically, have in many instances a common pathophysiologic factor, namely, bronchial or bronchiolar obstruction. Owing to spasm, edematous swelling, or collapse or distortion of the lumen, the smaller bronchial tubes and alveolar ducts mechanically hinder the movement of air in and out of the alveolar spaces. The existence of bronchiolar spasm in cases of emphysema was discussed by Hoover,²² who employed epinephrine as a measure of its presence. Richards and Kournand²³ have taken measurements that show significant increases in vital capacity after epinephrine. The therapeutic usefulness of helium is therefore based primarily on the existence of varying degrees of obstruction in these cases. There is the additional theoretical assumption that better oxygenation will take place with the employment of a 21 per cent oxygen-79 per cent helium mixture than with air, because of the increased diffusion of the lighter gas. In figure 4 a comparison is made between inhaling successively air, 100 per cent oxygen, and a 21 per cent oxygen-79 per cent helium mixture (the latter with 8 cm. of water pressure). It will be seen that the pulmonary ventilation in air was 15,750 cc. per minute with a tidal volume of 716 cc., in 100 per cent oxygen the pulmonary ventilation dropped to 10,700 cc., with a tidal volume of 563 cc., with 21 per cent oxygen-79 per cent helium the pulmonary ventilation was 10,640 cc., the tidal volume 444 cc. The marked drop in ventilation due to 100 per cent oxygen is the basis for the therapeutic reconditioning of these patients and is worth emphasizing, because of the common medical attitude of apathy and hopelessness toward these patients. As discussed earlier in the paper, the stretching of the elastic elements of the lung during inspiration is in my view the pathophysiologic factor in the production of emphysema. Such an obvious reduction in ventilatory needs as the foregoing test indicated was made the basis of oxygen treatment, which in a week lowered the ventilation still further to 6 liters per

minute. The paroxysmal cough that these patients endure appears to be in part maintained by anoxemia. Coughing raises the intra-alveolar oxygen concentration and also tends to inflate partially collapsed bronchioles. In cases under our observation, oxygen treatment has terminated or markedly decreased not only the cough but also the expectoration, which is frequently not the cause of coughing but a result.

The decrease in tidal volume and pulmonary ventilation during the inhalation of helium with oxygen is in part due to the increased pressure, but patients with emphysema in certain instances may become equally free from dyspnea by breathing either 100 per cent oxygen or 25 per cent oxygen and 75 per cent helium, illustrating the function of helium in counteracting the obstructive element in this condition.²⁴ In two cases, one of emphysema and one of asthma, in which an accidental pneumothorax had taken place, an exceedingly severe type of dyspnea resulted in which a mixture of 35 per cent oxygen and 65 per cent helium was followed by a degree of relief not obtained by pure oxygen or higher percentages of helium with lower oxygen concentrations.

For the more long continued treatment of emphysema, in which I now employ oxygen, the use of helium with oxygen would have substantial advantages. Sometimes the dyspnea of emphysema is not relieved until concentrations between 90 and 100 per cent oxygen are inhaled, when a similar degree of relief could have been obtained with lower oxygen percentages in the presence of helium instead of nitrogen. The present

Fig. 4.—Decrease in pulmonary ventilation in a patient with emphysema and pulmonary fibrosis due to inhalation of (1) oxygen and (2) helium with oxygen under positive pressure.

price of helium, until the government makes available a small part of its enormous supply, makes impracticable at the moment any long continued program of treatment of the emphysematous patient with helium oxygen mixtures instead of pure oxygen.

SUMMARY AND CONCLUSIONS

Because of the low density of helium, a respirable mixture of helium with oxygen requires considerably less effort to breathe than air or oxygen in patients suffering from obstructive dyspnea.

There were eighteen cases of severe asthma and twenty-one cases of obstruction in the upper air passages in this series. In status asthmaticus the treatment may result in the saving of life, five cases in the series seem

24. The helpful effect of positive pressure in expiration as well as inspiration in patients with asthma and emphysema explains the clinical observation that some patients will purse their lips in such a way as to create an obstruction to expiration as if they were blowing against resistance. The purposeful nature of this at first sight extraordinary performance is confirmed by their own confession that they feel "easier" in their breathing. The groan in pneumonia seems to me to have a purposeful significance also. It builds up a positive expiratory pressure against the pulmonary capillaries tending to prevent exudation of serum into the alveoli. As will be described in a subsequent publication, pulmonary edema is susceptible of prevention in animals and relief in man by inhalation of air under positive pressure.

23. Richards, D. W., and Kournand, A., to be published.

ingly being in this group, in severe, more or less continuous asthma, in an amelioration of the disease with recovery of complete sensitiveness to epinephrine in patients who previously had become refractory to it, as occurred in ten additional cases. In obstruction of the pulmonary airway from the bronchiole to the pharynx, inhalation of helium with oxygen lessens the respiratory effort and aids ventilation of the lungs, in some instances thereby averting tracheotomy, five patients in this series recovered without tracheotomy. In patients in whom the obstruction is below the trachea, dyspnea may be relieved when tracheotomy itself would be unavailing.

The usefulness of helium with oxygen in emphysema, associated with bronchiectasis or fibrosis or both, is compared to the procedure when oxygen treatment alone is employed. Smaller concentrations of oxygen may produce similar restoration of pulmonary function when helium is used as the diluent of oxygen instead of nitrogen.

The clinical reaction to inhalation of helium with oxygen may be used as a diagnostic procedure to determine the presence or absence of obstruction in the pulmonary airway and associated pulmonary functions.

893 Park Avenue.

ABSTRACT OF DISCUSSION

DR. FRANCIS M. RACKEMANN, Boston. It is obvious that Dr. Barach has presented an important method for the treatment of very difficult situations. I should like to emphasize one point about asthma, namely, that the pathology depends on the formation of very tough and very tenacious mucous plugs in the medium sized and smaller bronchi. These plugs cause obstruction, which may be complete, producing real asphyxia, and death is not unknown. Patients with this condition may therefore be in very real danger. Up to now, their treatment has been very difficult, but those of us who must take care of patients with severe asthma should be very grateful to Dr. Barach for giving us this new method. His observations on the effect of increasing the pressure of the inspired air confirms the clinical impression that the sucking or pulling action of the thorax is much more potent in producing the symptoms and producing the emphysema than is the pushing action of forced expiration.

DR. C. K. MAYTUM, Rochester, Minn. I congratulate Dr. Barach for presenting a most valuable method for relieving the symptoms of patients suffering from severe respiratory obstruction. My experience with helium and oxygen has not been as extensive as Dr. Barach's. I have used it only in the severest cases of asthma that is in the so-called status asthmaticus and the severe asthmatic attacks that follow the ingestion of certain drugs to which the patient is sensitive, in our cases acetyl-salicylic acid. I have used it only as a last resort when all other methods have failed to relieve the patient's symptoms. I have now used it in four cases, and the results have been satisfactory and confirm those of Dr. Barach. Oxygen alone in such cases does very little either toward relieving the dyspnea or the cyanosis that is also present. However, in my cases, as with Dr. Barach's, when helium and oxygen was substituted for mixtures of air and oxygen, relief was almost immediately apparent. The breathing becomes much easier, with much less effort, and the patient can relax, which is an important factor in overcoming the symptoms in these cases. The cyanosis gradually lessens and the attack gradually subsides. My patients also seem to be insensitive to epinephrine. Even large doses give little relief, and what relief is obtained is of very short duration. In my cases also, after the relief of the attack, the patients again reacted to the use of epinephrine in the ordinary dosage. I noted the same effect in 1931, in a few cases in which I relieved patients by colonic ether anesthesia. These patients, after relief from their asthmatic attacks, again became sensitive to epinephrine. It is unfortunate that the expense of helium and the technical difficulties in its administration must at least at present limit

its use. I hope that future developments will make it more generally available and that there will be a substantial reduction in its cost.

DR. JOHN D. KERNAN, New York. There are many cases of transient laryngeal dyspnea, occurring principally in children, in which the attending physician feels that neither intubation nor tracheotomy is required. And yet these cases are distressing to observe, and the suffering of the patient is considerable. Helium and oxygen will promptly relieve them. There is another type of case in which the amount of obstruction is no greater than in the first class but in which the long continued obstruction is a source of danger. Lack of sleep, lack of ability to eat and take fluids, and the strain on the circulation tend after a certain time to exhaust the patient. These are cases in which intubation might be used. The use of helium and oxygen makes the use of intubation with its attendant dangers of bronchopneumonia and retention of the tube unnecessary. Even a few hours in the helium-oxygen tent would so restore the child's strength that further gas therapy would be unnecessary, although the obstruction to the breathing might not be entirely relieved. In cases of greater obstruction in which a tracheotomy might be required, the patient will often be carried along for several days. Prolonged treatment is not practical in those cases in which the cause of the obstruction may be permanent, such as in congenital narrowing of the trachea, tumors or webs in the larynx. These patients must be tracheotomized. But even here the gas therapy is of the greatest use, since doing a tracheotomy on a patient moribund from strangulation and exhaustion is a very different procedure from a tracheotomy performed on a patient protected from exhaustion by the use of the gases. That is one of the most important uses of helium and oxygen in laryngeal obstruction. Many patients are admitted to the hospital almost at the point of death, cyanotic, the lungs congested and heart dilated. These symptoms may be temporarily relieved by inhalations, the patient taken to the operating room with a gas mask on the face, and the operation done under as favorable circumstances as possible. The only relief that can be compared to this is that obtained by the passage of the bronchoscope and the performance of a tracheotomy with the bronchoscope in position. Briefly, helium-oxygen therapy is indicated (1) for the relief of symptoms even when intubation or tracheotomy is not required, (2) in more severe cases in which intubation or tracheotomy would be required if the gas were not available, and (3) in cases of such severe dyspnea that tracheotomy is required and yet on account of the severity of the symptoms cannot be safely done.

DR. FRANK H. LAHEY, Boston. I did not come to the medical section to relate my experiences with the management of asthma but rather to express my appreciation to Dr. Barach for the development of this method of introducing oxygen in patients who are so greatly in need of it, and to relate also the experience of our anesthetists who have taken up this suggestion of Dr. Barach and who now advantageously employ helium in certain of the cases with which we have to deal, goitrous patients with narrow tracheas, those with goiters that are intrathoracic in location and those with the respiratory emergencies which not infrequently arise in thyroid surgery. Drs. Sise, Woodbridge and Eversole have now employed helium in a considerable number of cases. I am sure that within the last six months helium has saved the lives of at least three patients who have come to the clinic for operation with enormous intrathoracic goiters. When we have these very large and very deep intrathoracic goiters, extending sometimes nearly to the diaphragm, it becomes almost impossible to introduce an intratracheal catheter because of the distortion of the trachea. It therefore becomes almost impossible to have these patients get enough oxygen when anesthetized so that they can remain of good color. The employment of helium mixed with oxygen in these cases has resulted in a good return of color and permitted the operation to be completed. In emergencies in which there has been a collapse of the trachea in the middle of an operation on a goiter, the employment of helium and oxygen mixtures has permitted these patients to be put in such a condition that the intratracheal catheter could be introduced through the laryngoscope and the operation completed. I am prompted to come here and speak because of the possibility

that anesthetists throughout the country are not familiar with this application of helium and are not employing it in cases in which I am sure that it will save patients' lives. We now have a tank of helium attached to every anesthesia apparatus in the clinic because, when one has such an emergency, helium should be at hand and immediately available. This is a great advance. We surgeons are indebted to Dr. Barach, and I am sure that not only with asthmatic cases but with surgical cases it will save many lives.

DR. WILLIAM J. KERR, San Francisco. In our clinic we have had but a limited experience in the use of helium and oxygen in obstructions of the respiratory tract, but we have been very much interested and pleased with the results to date. In patients with obstruction or asthma the relief is often remarkable and the patient appears to be greatly benefited by the rest obtained and the ability to take proper nourishment. I hope that in the very near future some way will be found to have adequate equipment available in all hospitals for the use of helium equipment available in all hospitals for the use of helium or helium and oxygen, and that we shall be able to secure supplies from the one source in the country where it may be obtained and at a very nominal figure and that is from the federal government. It seems to me that helium should be put in the hands of competent physicians, because it is one of the adjuncts in saving lives.

DR. ALVAN L. BARACH, New York. The House of Representatives has passed a bill making government helium available at what will be a cost comparable to oxygen, but at the moment it is held up in the appropriations committee of the United States Senate. Whether it will go through there or not, at this moment I am unable to tell. Should it be passed in its original form, helium will be commonly available at a more reasonable cost, although it may now be obtained commercially and reused with more economy than when it was first presented.

PRESENT STATUS OF DIETARY REGIMENS IN URINARY INFECTIONS

ANSON L. CLARK, M.D.
OKLAHOMA CITY

Urology, as one of the younger medical specialties, has made rapid advances and has a record of brilliant achievement. During the last forty years the surgical and diagnostic branches, aided by the inventive genius of men within and without the profession, have produced remarkable results. The medical side of urology, on the contrary, had advanced more slowly. Modern textbooks of urology attest to the rapid change in surgical practice and instrumental technic, but the lack of advance in the medical branch left open a fertile field for charlatans and drug promoters.

During the last five years, however, medical urology has progressed in two ways: first by a more careful study of the organisms most frequently associated with urologic infections, and, second, by attempts at inhibiting the growth of those organisms with dietary therapy. In studying the causes and prevention of urinary calculi, emphasis has been placed on other causes besides the important fundamental one, namely, urinary stasis. Endocrine disturbances have been recognized as being a contributing factor, but dietetic excesses and deficiencies have proved of greatest importance.

Theoretically, the etiologic factors of infections of the urinary tract and urinary calculi are many and varied, but it is now recognized that trauma from crystalline elements formed in the kidney may be a contributing cause. For instance it is well known that certain foods produce an increase in the calcium

oxalate content of the urine. There is also another source of an oxaluria. Wilder states that, "in the presence of certain unusual flora oxalic acid and other organic acids may be formed by fermentation of carbohydrates in the gastro-intestinal tract." The extensive use of yeast so popularly advertised may thus be a cause of increasing the crystalline elements in the urine. Several patients have been observed who passed numerous small oxalate calculi following the prolonged ingestion of yeast. With the excessive fermentation that must follow a diet containing a cake of yeast three times a day, sufficient change in carbohydrate metabolism may take place to increase the oxalates in the urine to a dangerous amount.

While important advances have been made in therapeutic measures involving the study of foods, and their preparation and combination, it must be pointed out that only a small portion of the population is being benefited at present by these recent discoveries. This is largely due to a lack of time necessary to apply this knowledge. When the average physician undertakes the complex problem of figuring the calories, carbohydrates, proteins, fats, fatty acid-dextrose ratio and 3 per cent vegetables and then adds to this the task of training a patient who, though interested, knows nothing of scientific food regulation, one understands the frequent use of the prescription blank in combating infections of the urinary tract. But the results produced by dietetics in urology have been sufficiently successful to make it imperative that this type of treatment be made more widely available. Wherever it is possible, these measures should be so simplified as to make them applicable to office practice. Hospitalization, diet kitchens and special dietary management, as applied in large medical centers, increase the cost of treatment till it becomes prohibitive for the majority of those afflicted.

Five years ago for the first time the ketogenic diet was given to a patient in an effort to control a very resistant recurrent cystitis and pyelitis in which the infecting organism was the colon bacillus.¹ For fourteen months previous to this, many different types of therapy had been applied at several medical centers with only temporary relief to the patient. The products of the ketogenic diet permanently eliminated the infecting organism from the urine in twelve days.

Since that time the result achieved in that one case has stimulated many other experiments and investigations. In an analysis of the first 200 instances in which this type of therapy was used, it was found successful in approximately two out of three instances. Statistics show that the ketogenic treatment has been even more successful in the child, possibly because the liver of the adult has a greater glycogen storage capacity.

Fuller² of London was the first to discover that beta-hydroxybutyric acid excreted in the urine by this altered dietary intake inhibited the growth of the infecting organism. It had already been recognized that, in addition to the change in diet, an increased acidity of the urine was a necessity for successful results. Several authors then reported experiments which showed that bacterial growth in the urinary tract would be inhibited by a concentration in the urine of 0.5 per cent beta-hydroxybutyric acid, and an acidity of the urine of pH 5.2.

Two years ago an evaluation of the ketogenic treatment showed that its scope was limited. Many sufferers

from pyelitis or cystitis were unable to obtain careful and exact dietetic supervision. Accordingly a simplified method of dietary regimen was suggested in which the food intake consisted largely of 40 per cent cream and eggs.³ The disadvantage of this simplified method is the gastro-intestinal upset that usually accompanies such an abnormal food intake. As an offset to this the

TABLE 1—*Elaborate Ketogenic Diet*

GENERAL INSTRUCTIONS

- 1 Satisfactory results cannot be obtained unless this diet is followed absolutely as outlined.
- 2 All food must be measured carefully and accurately. A standard measuring cup, teaspoon and tablespoon must be used.
- 3 No food or beverage other than that listed is to be taken.
- 4 Eat no sugars or sweets of any kind. Saccharin a substitute for sugar may be used.
- 5 Coffee, tea and seasonings may be used as desired.
- 6 Bran wafers must have no food value and may be used as desired.
- 7 Do not chew gum or tobacco. Smoking is permitted.
- 8 Water should be taken only in moderate amounts.
- 9 No cathartics are to be used other than liquid petrolatum or bitter cascara. Magnesia magma or other sweet cathartics will cause failures.
- 10 Take no medicine unless prescribed by the physician.
- 11 If you become nauseated while on the diet omit a meal or two taking a half glass of tomato juice, half an orange or a glass of sour lemonade.

MENU PLAN

Include the following foods daily and in the exact amounts specified.

Eggs	Two
Bacon	4 strips 6 inches long
Vegetables	1½ cups
Whipping cream (extra heavy)	1¼ cups
Butter or oil mayonnaise	5 tablespoons
Meat	2½ ounces or 3" by 4" by ¼" thick

Menus 1, 2, 3 and 4 suggest possible combinations. Many interesting menus may be planned however when different vegetables are used and eggs and cream are prepared in various dishes.

POSSIBLE SUBSTITUTIONS

- 1 2 tablespoons of cottage cheese plus 1 teaspoon of butter or oil mayonnaise may be substituted for one egg.
- 2 One ounce of American cheese or meat may be substituted for one egg.
- 3 ½ of a small orange may be substituted for ¼ cup of vegetables.

VEGETABLE LIST

Asparagus	Greens beet
Beans string	Greens mustard
Broccoli	Greens turnip
Brussels sprouts	Green peppers
Cauliflower	Rhubarb
Celery	Sauerkraut
Cucumbers	Spinach
Egg plant	Tomatoes

BREAKFAST

MENU 1

Egg fried	One
Bacon	4 strips 6" long
Bran wafers	As desired
Butter	1 tablespoon
Heavy whipping cream	¼ cup
Coffee or tea	If desired

LUNCH

Soup	
Heavy whipping cream	¾ cup
Tomato	½ cup
Seasoning	
Salad	
Hard cooked egg on	One
Lettuce leaf	One
Oil mayonnaise	1 tablespoon
Bran wafers	As desired
Butter	1 tablespoon

DINNER

Roast pork	3" x 4" x ¼"
Creamed cauliflower	
Cauliflower	½ cup
Heavy whipping cream	¼ cup
Lettuce salad	½ cup
Oil mayonnaise	1 tablespoon
Bran wafers	As desired
Butter	1 tablespoon

BREAKFAST

MENU 2

Egg poached	One
Bacon	4 strips 6" long
Bran wafers	As desired
Butter	1 tablespoon
Heavy whipping cream	¼ cup
Coffee or tea	As desired

LUNCH

Soup	
Celery diced	¾ cup
Heavy whipping cream	¾ cup
Water	¾ cup
Salad	
Orange sections	½ of a small orange
Oil mayonnaise	1 tablespoon
Lettuce leaf	One
Bran wafers	As desired
Butter	1 tablespoon

DINNER

Broiled steak	3" x 4" x ¼"
String beans	½ cup
Lettuce salad	½ cup
Oil mayonnaise	1 tablespoon
Bran wafers	As desired
Butter	1 tablespoon
Baked custard or custard ice cream	
Egg	One
Heavy whipping cream	½ cup
Water	¼ cup
Nutmeg & saccharin	If desired

BREAKFAST

MENU 3

Scrambled eggs	
Egg	Two
Heavy whipping cream	¼ cup
Bran wafers	As desired
Butter	1 tablespoon
Heavy whipping cream	¼ cup
Coffee or tea	As desired

LUNCH

Crisp bacon	4 strips 6" long
Spinach	½ cup
Lettuce and tomato salad	½ cup
Oil mayonnaise	1 tablespoon
Bran wafers	As desired
Butter	1 tablespoon
Iced coffee	
Coffee	As desired
Heavy whipping cream	¼ cup

DINNER

Fish	3" x 4" x ¼"
Creamed celery	
Celery	½ cup
Heavy whipping cream	½ cup
Bran wafers	As desired
Butter	2 tablespoons

BREAKFAST

MENU 4

Tomato juice	½ glass
Bacon	4 strips 6" long
Bran wafers	As desired
Butter	2 tablespoons
Heavy whipping cream	¼ cup
Coffee or tea	As desired

LUNCH

Egg omelet	
Egg	One
Heavy whipping cream	2 tablespoons
Butter	2 tablespoons
Seasoning	As desired
Asparagus	½ cup
Cottage cheese salad	
Cottage cheese	2 heaping tablespoons
Heavy whipping cream	2 tablespoons
Oil mayonnaise	1 teaspoon
Bran wafers	As desired
Butter	2 tablespoons

DINNER

Soup	
Heavy whipping cream	¾ cup
Spinach or tomato	¼ cup
Water	¼ cup
Chicken salad	
Diced chicken	½ cup
Diced celery	¼ cup
Lettuce leaf	One
Oil mayonnaise	2 tablespoons
Bran wafers	As desired
Butter	2 tablespoons

course of treatment is shortened, thus minimizing the expense as to both time of medical supervision and dietary cost.

Nesbit⁴ of Ann Arbor, Mich., suggested applying the acidosis and ketosis produced by a starvation diet to the treatment of infections of the urinary tract. In a series of 200 patients given this type of ketogenic diet, remarkable results were shown. The drawback to the starvation method is the length of time necessary to obtain ketosis sufficient to achieve satisfactory results. This is important in office practice. The

3 Clark, A. L. and Keltz, B. F. A Simplified Treatment of Bacilluria. J. A. M. A. 104: 289-291 (Jan. 26) 1935.

4 Nesbit, R. M. Low Calory Low Fat Ketogenic Diet for Treatment of Infections of Urinary Tract. J. A. M. A. 105: 1183-1184 (Oct. 12) 1935.

advantage of the starvation ketosis diet lies in the gastro-intestinal comfort of the patient. Nesbit maintains that after the first forty-eight hours the pangs of hunger are slight.

Herrold⁵ has suggested a still more limited food intake which makes it possible to use the low calory ketogenic diet as an office procedure. So today for

TABLE 2—Simplified Ketogenic Diet

General Instructions as in table 1

MENU PLAN

Include the following foods daily in the exact amounts specified

Heavy whipping cream 1½ pints (3 cups)
Eggs Six

Any combination of two eggs and one cup of cream may be used at each meal. Below are three suggestions. If desired some cream may be used between meals with coffee or tea.

BREAKFAST

Scrambled eggs Two
Eggs ¾ cup
Heavy whipping cream As desired
Bran wafers ¾ cup
Heavy whipping cream As desired
Butter As desired
Coffee or tea As desired

LUNCH

Poached egg One
Baked custard or custard ice cream
Egg One
Heavy whipping cream 1 cup
Water ¼ cup
Nutmeg and saccharin If desired
Bran wafers As desired
Butter As desired

DINNER

Egg omelet Two
Eggs ¾ cup
Heavy whipping cream As desired
Bran wafers ¾ cup
Iced coffee As desired
Coffee ¾ cup
Heavy whipping cream As desired
Butter As desired

combating infections of the urinary tract there is available a simplified ketogenic diet, an elaborate ketogenic diet and a low calory ketogenic diet, each with its particular advantages but all producing results in medical urology hitherto not achieved.

Table 1 contains a suggestion for an elaborate ketogenic diet with a fatty acid-dextrose ratio of 4:1. It is essential that the list of important instructions be emphasized to the patient. A simplified ketogenic diet is suggested in table 2 and a low calory ketogenic diet, with sample menus, is given in table 3⁶.

In this day of rapid advances it is most probable that scientific research, having discovered the reason for the success of these dietary measures in combating infections, may lead to still greater simplification in urologic therapeutics. As already stated, Fuller recognized the important part played by beta-hydroxybutyric acid in inhibiting the growth of bacterial invaders. Starting with this fact, Rosenheim⁷ suggested that a keto or hydroxy acid, if nontoxic, which would be excreted unchanged in the urine might replace the ketogenic diet. After considering a number of such acids and comparing them with beta-hydroxybutyric acid in respect to their bacteriostatic powers in vitro, he has found that mandelic acid fulfils the theoretical requirements better than any of the other similar agents. This acid is a hydroxy acid, it is nontoxic and is excreted unaltered in the urine, which it renders bacteriostatic. The adult dosage suggested is 12 Gm. of mandelic acid daily in divided doses. At the same time the acidity of the urine is increased by giving either ammonium

nitrate or ammonium chloride orally. Mandelic acid is soluble in water and is most satisfactorily given in the form of a sodium salt. From a 16 ounce (480 cc.) mixture containing 48 Gm. of mandelic acid (neutralized by 25.6 Gm. of sodium bicarbonate and flavored as desired), 1 ounce (30 cc.) is given four times a day as an average adult dose. With this, from 6 to 8 Gm. of ammonium chloride may be given daily in divided doses. During this medication the patient takes his normal general diet. From the results in a small series of patients it is apparent that the bacteriostatic power of the urine containing mandelic acid is sufficient to recommend this type of therapy before a diet is employed which causes such gastro-intestinal discomfort as does the ketogenic diet.

The sodium salt of mandelic acid is not unpleasant to take, and the only objection to this treatment is the large doses of ammonium chloride prescribed in conjunction with the acid. In my practice it has been employed with patients of various ages, from 3 years

TABLE 3—Low Calory Ketogenic Diet

General instructions as in table 1 and 2 except that butter or oil mayonnaise may be used in any quantity desired to make the diet more palatable.

MENU PLAN

Include the following foods daily and in the exact amounts specified

Eggs Two
Crisp bacon 4 strips 6" long
Lean meat 2½ ounces or 3" x 4" x ¼" thick
Vegetables (from list below) 2 cups
Whole milk or buttermilk ½ cup
Butter or oil mayonnaise 3 teaspoons or more if desired

Possible substitutions same as in table 1
Vegetable list same as in table 1

BREAKFAST

MENU 1

Tomato juice ½ cup
Egg scrambled One
Bacon crisp 4 strips 6" long
Bran wafers As desired
Butter 1 teaspoon
Coffee or tea As desired

LUNCH

Cauliflower ½ cup
Salad
Sectioned orange ½ of a small orange
Lettuce leaf One
Bran wafers As desired
Butter or oil mayonnaise 1 teaspoon
Baked custard
Egg One
Whole milk ½ cup
Nutmeg or saccharin If desired

DINNER

Broiled steak 3" x 4" x ¼"
Asparagus ½ cup
Bran wafers As desired
Butter 1 teaspoon

BREAKFAST

MENU 2

Orange ½ of a small orange
Poached egg One
Crisp bacon 4 strips 6" long
Bran wafers As desired
Butter 1 teaspoon
Coffee or tea If desired

LUNCH

Spinach ½ cup
with
Hard cooked egg One
Bran wafers As desired
Butter 1 teaspoon
Whole milk ½ cup

DINNER

Roast beef 3" x 2" x ¼"
String beans ½ cup
Shredded lettuce ½ cup
Oil mayonnaise If desired
Bran wafers If desired
Butter 1 teaspoon
Tea If desired

BREAKFAST

MENU 3

Egg soft cooked One
Bacon crisp 4 strips 6" long
Bran wafers As desired
Butter 1 teaspoon
Coffee or tea As desired

5 Herrold, Russell to be published.

6 The author is indebted to Mrs. Marjorie Sewell, chief dietitian at the University Hospital, Oklahoma City, for her help and advice in the preparation of these diets and menus.

7 Rosenheim M. L. Lancet 1 1032 1037 (May 4) 1935

LUNCH

Soup	
Whole milk	$\frac{1}{2}$ cup
Celery diced	$\frac{1}{4}$ cup
Egg omelet	1 egg
Greens	$\frac{1}{4}$ cup
Bran wafers	As desired
Butter	1 teaspoon

DINNER

Baked fish	3" x 4" x $\frac{1}{4}$ "
Stewed tomatoes	$\frac{1}{2}$ cup
Lettuce shredded	$\frac{1}{2}$ cup
Oil mayonnaise	If desired
Bran wafers	As desired
Butter	1 teaspoon

BREAKFAST

MENU 4

Orange	$\frac{1}{2}$ of a small orange
Eggs scrambled	Two
Bran wafers	As desired
Butter	1 teaspoon
Coffee or tea	As desired

LUNCH

Butter	1 teaspoon

to 76 years, with no apparent toxic effects. The 3 year old child had had an acute bacillary cystitis and pyelitis four weeks before the mandelic acid was tried. At this time the infection was controlled to some extent with methenamine and sodium acid phosphate, but the infecting organism still remained in the urinary tract. A dosage for a 3 year old child, based on the adult dosage given, was prescribed for three days. The urine culture on the third day was sterile and the medication was discontinued. The patient has remained well.

In older patients it is necessary to continue the drug for considerably longer periods. Further studies as to the rapidity with which this acid is excreted by the kidneys will be necessary in order that the drug may be prescribed at just the right intervals to insure the highest uniform concentration in the urine during the twenty-four hour period.

The mandelic acid treatment seems to be another valuable addition to the armamentarium of urology, which has resulted from a closer cooperation with and better knowledge of dietetics.

SUMMARY AND CONCLUSIONS

- 1 Prolonged ingestion of yeast should be considered as a possible factor when calculi or an excessive amount of crystalline elements are present in the urinary tract.
- 2 It is essential that dietary therapy be simplified in order to reach the largest number of patients suffering from uncomplicated bacillary infections of the urinary tract.
- 3 Mandelic acid has proved to be an effective urinary antiseptic and should be tried before the ketogenic diet.

119 North Broadway

ABSTRACT OF DISCUSSION

DR. WILLIAM F. BRAASCH, Rochester, Minn. Dr. Clark was first in calling attention to the practical value of the ketogenic diet in treating urinary infection. Although this method has proved to be highly efficacious unfortunately the technical difficulties involved in its application have prevented widespread employment. Simplification of the diet and adap-

tation to the patient's idiosyncrasies as well as other modifications, including those suggested by Nesbit, have made it more acceptable for general use. The ketogenic diet is apparently of value not alone in combating urinary infection. There is evidence that it may be of value in controlling infections in other portions of the body. I have observed several patients with pyelonephritis and coincident acute cholecystitis which were apparently controlled by means of the ketogenic diet. Efficient as ketosis proved to be in combating bacilluria, it is after all a crude and ponderous method of establishing urinary antiseptics. Although American urologists were first to show the bactericidal effect of ketonuria, it remained for English chemists to discover the chemical ingredients that caused it. When Fuller discovered that beta-oxybutyric acid was the bactericidal factor in ketonuria, he opened a new and promising field of urinary antiseptics. Rosenheim, in searching for an organic acid which could be assimilated and excreted without breaking down, discovered that mandelic acid had antiseptic qualities when excreted in the urine, similar to beta-oxybutyric acid. My associates and I have used mandelic acid in both children and adults in more than fifty cases. Judging from our experience, it is quite probable that it will largely supplant the ketogenic diet as a routine procedure. That it will displace it entirely, however, is open to doubt. It has been possible to effect complete disappearance of bacteria from the urine in many of our patients with urinary infection. However, it does not seem to be so thorough as ketosis in preventing reappearance of infection, since bacteriuria reappeared in some cases after several weeks. The two methods combined will be found to be more bactericidal than when either is used alone. In order to have bactericidal action, acidification of the urine will be necessary with mandelic acid as it has been with oxybutyric acid. Mandelic acid together with the ketogenic diet, the high acid-ash diet, and the various modifications will unquestionably make it possible to control urinary infection in a high percentage of cases, particularly that group which has no complications. A new era of antiseptics has been revealed within the last few years, and progress along the lines of urinary acidification, together with organic acid elimination in the urine, present attractive vistas for further investigation.

DR. RICHARD CHUTE, Boston. I have had the opportunity of seeing the use of mandelic acid in a few cases with apparently brilliant results. The cases have been so few and followed for such a short time that I am unable to give any final data on them. I think, however, that a great deal will be heard about it in the next few years.

DR. CHARLES C. HIGGINS, Cleveland. Vitamin A is prescribed for two reasons: (1) to overcome deficiency in vitamin A if it is present and (2) for its specific effect on the epithelial structures. This effect is specific not only on the epithelium of the genito-urinary tract but also on the epithelium of the pulmonary and other mucous membranes. In the presence of vitamin A deficiency in the white rat the pH of the urine shifts strongly to the alkaline side, therefore the stones that are produced experimentally in the white rat are composed of calcium phosphate with traces of carbonate. If the phosphorus in the diet is decreased, a reversal in the chemical composition of the stone occurs and calcium carbonate with traces of phosphate are found. In patients, if a deficiency in vitamin A is present, it is not accompanied by a shift in the pH of the urine to the alkaline side. As Dr. Braasch has emphasized the dietary regimen is an additional procedure to be utilized in the management of patients with calculous disease. Obviously, infection must be eradicated, and I believe this should be accomplished before the patient leaves the hospital. In patients in whom we are able to demonstrate the presence of a urea splitting infection we prescribe the ketogenic diet following operation. As soon as the infection is eradicated we shift from the ketogenic diet over to the acid ash diet, which is not conducive to the production of acetone, diacetic acid or beta-oxybutyric acid in the urine or the alkaline ash diet is prescribed. Whether the high vitamin A acid ash or alkaline ash diet is prescribed depends on the pH of the urine secured from the kidney harboring the calculus and the chemical composition of the stone removed at operation. The patient can be maintained on these diets for a long period of time. It is important to remember that the acid-ash diet is not utilized

in all cases of calculous disease. If analysis of the stone shows it to be composed of cystine, xanthine or uric acid—salts that are precipitated in acid urine—the pH must be shifted to the alkaline side postoperatively. A pH of 6.8 suffices to maintain the uric acid and other acid salts in complete solution and below the point at which precipitation of phosphates and carbonates occurs. If stasis is demonstrated by the urogram, it must be correct postoperatively. A study of the pH curves of normal individuals and those with calculous disease shows that the initial precipitation of salts in the urine occurs at approximately the same level, however, I believe that each patient should be individualized, the urine carefully examined, and the pH estimated and maintained at a point at which the salts that are responsible for the formation of the original calculi are maintained in complete solution.

DR J. K. ORMOND, Detroit. I should like to ask whether this mandelic acid is effective in coccic infections as well as in bacterial infections.

DR ANSON L. CLARK, Oklahoma City. In answering the question of Dr Ormond apparently mandelic acid acts as a bacteriostatic agent in a rather similar way to the beta-hydroxybutyric acid produced by the ketogenic diet. In the adults it has been most successfully used in combating the bacillary infections while in children it has been used satisfactorily in both the bacillary and the coccic types of infection. Patients in the younger age bracket must be able to excrete the mandelic acid in a larger concentration. At present mandelic acid is a high priced chemical, at wholesale prices costing about \$45 a kilogram. To treat an adult patient from eight to ten days requires approximately 100 Gm of the mandelic acid.

BRODIE'S ABSCESS OF RADIUS, DUE TO TYPHOID

REPORT OF A CASE

WILLIAM B. MARBURY, M.D.
AND
HENRY L. PECKHAM, M.D.
WASHINGTON, D. C.

Typhoid of the bones is one of the unusual types of inflammatory bone diseases. To be more specific, Murphy¹ states that out of a series of 700 cases of osteomyelitis only three were caused by typhoid. This amounts to 0.43 per cent, or one out of 233 cases. Also osteomyelitis complicating typhoid is not at all common, for in another series of cases of typhoid reported by Murphy there were only 164 cases of osteomyelitis complicating 18,840 cases of typhoid, or 0.82 per cent. So uncommon is this condition that it is not usually suspected unless there is a definite history of typhoid and the constitutional symptoms of the osteomyelitis are unusually mild, even then it is not often thought of until the bacteriologist grows typhoid bacilli from the pus.

The various bones of the skeleton vary in their susceptibility to typhoid invasion, and in a different way from their variation of susceptibility to the common pyogenic organisms, such as the staphylococcus and the streptococcus. Thus the ribs are the most common bones involved in a typhoid osteomyelitis, with the tibia holding second place and the spinal column third place. In a series of 533 typhoid bone lesions, the ribs were involved in 135 cases, the tibia in 127, the spine in 110, the femur in 33, the ulna in 18, the humerus in 15, the foot in 10, the pelvis in 9, the maxilla in 8, the sternum, clavicle and hand each in 7, the radius in 5, and the rest distributed among the remaining bones. The case that

we are presenting in this paper is one involving the radius, a bone which is involved only once in 106 cases of osteomyelitis due to typhoid, and the frequency of this disease is thus seen to occur only once in more than 24,000 cases of osteomyelitis from all causes.

In bone disease following typhoid the symptoms usually come on so late that the typhoid bacillus is seldom considered as the etiologic factor. Several cases have been reported in the literature in which the patients had typhoid anywhere from five to fourteen years before bone symptoms developed. The interval in the present case amounted to about ten years during which time the patient had no symptoms whatever of bone involvement.

The bacteria found in pus taken from these cases of typhoid osteomyelitis vary. In ninety-nine cases the organisms isolated from the pus were as follows: B. typhosus, 71, pyogenic organisms alone, 15, no organisms, 7, paratyphoid strains, 3, B. typhosus and pyogenic organisms together, 2, B. typhosus and B. coli together, 1.

In the case here reported, the pathologic lesion consisted of an abscess in the medulla of the radius. In other words, Brodie's abscess. This lesion was first described by Dr Brodie² in 1832, at which time he presented a paper before a medical society with several case reports. The manner in which he discovered this condition is interesting. His first patient was a man with intractable bone pain in the tibia, no remedy that Dr Brodie tried had any effect, so he finally decided to amputate the man's leg. Later on he examined the leg in the laboratory and, on cutting through the bone longitudinally, he opened an abscess from which he obtained a drachm or two of dark pus. Then he realized that the amputation would probably not have been necessary had he known of the presence of the bone abscess, and in his subsequent cases he operated and drained the abscesses with good results.

Babcock, in his textbook on surgery, defined Brodie's abscess as a "bone cavity filled with serum or pus lined by a fibrous membrane with surrounding sclerosed bone and a tendency toward obliteration of the adjacent medullary cavity." These abscesses usually occur nearer to the center of the metaphysis than toward its distal end, as is the case in acute pyogenic osteomyelitis.

The causative organism is usually the staphylococcus but may be the streptococcus, the pneumococcus, B. coli and rarely the typhoid bacillus. These organisms always arrive at the bone as a result of a hematologic metastasis from a distant focus of infection.

The symptoms of Brodie's abscess are boring, aching, osteocopic pain, referred to the center of the bone and aggravated by use, marked tenderness on pressure or percussion, intermittent limp, hydrops of the adjacent joint, and local enlargement of the bone and of the superficial veins. The overlying skin may be red and tense with edema of the subjacent tissues, and elevation of the skin temperature. Constitutional symptoms are usually few.

A roentgenogram usually shows an area of rarefaction, surrounded by an area of increased density of the bone.

The diagnosis of Brodie's abscess is often difficult to make preoperatively, with a bony swelling, marked tenderness, continuous boring osteocopic pain and absence of marked constitutional symptoms. This con-

¹ Murphy, J. B. Bone and Joint Disease in Relation to Typhoid Fever. Surg., Gynec. & Obst. 23: 119, 1916.

² Brodie, B. C. An Account of Some Cases of Chronic Abscess of the Tibia. M. Chir. Tr. 1: 238, 1832.

dition must always be kept in mind. In the differential diagnosis, gumma of the periosteum, malignant bone tumors, tuberculous periostitis and von Recklinghausen's disease are to be considered. Roentgen examination in these conditions is unusually helpful, as it gives a very distinctive picture in the various bone diseases.

The prognosis in Brodie's abscess is good if adequate drainage is supplied. Many times, however, especially in tuberculous or typhoid abscesses, a chronic sinus may remain for years. Many of them heal in the course of a few months.

Fig 1—Roentgen appearance of radius before operation.

leave the pack in place until the bone has regenerated considerably, as this stimulates the bone formation and keeps the wound from closing too soon, thus preventing recurrence of the same condition. In those abscesses due to typhoid, typhoid vaccine has been given to advantage.

REPORT OF CASE

History—H W, a girl aged 15 years white admitted to Emergency Hospital Dec. 6 1935, complained of pain and swelling of the lower part of the left forearm.

Her present illness dated back to two months before this admission at which time some pain and swelling developed in the left forearm. The swollen area was warm to the touch but showed no redness and after one week the inflammation subsided. Following this illness the patient was clinically well for two months. Then on December 2 four days prior to her entrance to the hospital a swelling appeared on the left forearm in the same place as the first one. This time the swelling was red, painful even when the arm was at rest, very tender and throbbed continuously, and the patient stated that she felt pins and needles in the fingers of the left hand. The patient had no general symptoms of note other than a subfebrile temperature of 99.6 F.

The past history revealed very little. Outside of measles and mumps there was one other disease of importance which was typhoid, at the age of 5 years.

Examination—On physical examination nothing was found except the local pathologic state of the left forearm. The tissues on the radial side of the forearm were tense and edematous at a point slightly below the junction of the lower and middle thirds. This swelling was very tender and appeared to be confined to the periradial tissues along the whole radial side of the forearm there was some pain elicited on palpation. The skin overlying the area was of a dusky red hue and the surface temperature was elevated. Almost any motion of the

forearm, especially pronation or supination, resulted in a cry from the patient, and she held the forearm as though it were broken.

At this time a roentgenogram was taken which revealed an oval, slightly irregular, dark, translucent area within the shaft of the radius (fig 1). The cortex around this dark area appeared to be somewhat thinner than that in the rest of the shaft and seemed to bulge outward slightly. The remainder of the bone appeared to be normal.

The impression at this time was that the patient had an infected bone cyst of some nature, or Brodie's abscess. Von Recklinghausen's disease of the bone was considered also as a possible diagnosis but blood calcium and phosphorus studies did not confirm this condition the calcium being 10 and the phosphorus 34, both of which are within normal limits.

Urinalysis consistently showed only a very faint trace of albumin and some clumped pus cells.

A blood count taken the day after admission showed a hemoglobin of 84 per cent, red blood cells 4,350,000 and white blood cells 10,100 of which 61 per cent were polymorphonuclears, 34 per cent lymphocytes, 4 per cent monocytes and 1 per cent eosinophils. The blood Wassermann reaction was negative.

Course—The patient remained in the hospital ten days before it was decided to operate. During this time the temperature at no time exceeded 99.8 F, and the last six days it was normal. The forearm was kept in a splint constantly, as the slightest motion was painful.

Operation—December 16 the patient was taken to the operating room and the forearm opened. The periosteum of the radius was pinkish and was softer and more vascular than usual. When the cortex was chiseled away pale greenish creamy pus was found under pressure within the cavity. The pus was evacuated and the interior of the cavity was swabbed with pure phenol followed by alcohol and packed open with petrolatum gauze. A cast was applied.

A smear made at the time of the operation showed many pus cells and a culture taken at the same time disclosed typhoid bacilli. Five days after the operation a blood Widal test was done and showed agglutination against B typhosus in dilutions ranging from 1 to 20 up as high as 1 to 320.

The postoperative course was uneventful and convalescence was rapid, there being no fever after the first postoperative day. December 23 a culture of the urine and feces was made here but no typhoid bacilli were found. December 25 a sample of feces was sent for culture to the Walter Reed General Hospital. The report again came back negative. December 27 the patient was discharged.

In much improved condition and was referred to the orthopedic clinic for follow-up care. When the patient left the hospital the pain in her arm had practically subsided when she was seen Feb. 11 1936 her arm felt well but was draining considerable serous material with a bad odor (Feb. 11 1936). January 24 the gauze packing was removed. The wound showed a marked healing tendency as shown by abundant healthy granulation tissue. January 27 an x-ray plate was taken (fig 2) and the report was as follows:

Fig 2—Roentgen appearance of radius after operation.

Examination of the left wrist and lower forearm shows the cortex of the lateral aspect of the lower third of the radius to have been perforated. There is a rather marked elevation of the periosteum on both the mesial and lateral aspects and considerable absorption in the region of the wrist joint.

This patient has been seen several times since the last x-ray film was taken. April 1, healing was complete and union firm. There was no tenderness over the scar.

COMMENT

This case is a most unusual one. It demonstrates clearly that typhoid bacilli may and do remain quiescent in the human body for many years only to be reactivated at a time when least suspected. The ability of the body to throw out antibodies quickly when reinfection occurs in typhoid is well shown by the high titer of the blood Vidal test in this case.

ADRENAL VIRILISM

WILLIAM SAPHIR, MD

AND

MORRIS L. PARKER, MD

CHICAGO

An active sex principle of the adrenal cortex has not yet been successfully elaborated. There is, however, ample clinical evidence that this endocrine tissue supplies an internal secretion related to the sexual sphere. The types of hypergonadism described in the literature as hirsutism, virilism, adrenogenital syndrome and the Achard-Thiers syndrome have been proved in many cases to be associated with adrenal cortex tumors.

It is not intended here to enter into a review of the literature, which may be found in some recent publications,¹ but to refer briefly to a few communications pertinent to this study.

From the clinical evidence at hand, the function of the adrenal sex hormone is clear and unique. It stimulates the secondary sex characteristics not of the same sex but of the opposite sex. Thus in women are seen male hair distribution (bearded women), deep voice, amenorrhea, atrophic breasts, atrophic genitalia with elongated penis-like clitoris (pseudohermaphroditism), in men a female type of obesity, breast hypertrophy with milk secretion, atrophy of testes, and absence of libido.

The adrenal sex hormone, therefore, is distinctly different from the pituitary sex hormone which stimulates the gonads and from the gonadal hormones, which stimulate the secondary sex characteristics of the same sex.

In the present paper we describe a case of suprarenal virilism in a woman who was closely studied clinically, physiologically and histologically. It is believed that some facts of interest were found that may clarify this syndrome more definitely and may be helpful in recognizing similar clinical manifestations.

REPORT OF CASE

History.—Miss M. G., aged 15, admitted to the Michael Reese Hospital service of Dr. M. L. Parker June 16, 1935, had never been sick before. The menses started at the age of 12, were regular and were of four weeks interval. The family history was insignificant. About one year before there was sudden onset of amenorrhea, a gain in weight of 30 pounds (136 kg.) growth of hair on the face, extremities and abdomen and a deepening of the voice. No pains or discom-

fort were felt at any time. The patient and her parents were alarmed about her condition which apparently was getting progressively worse.

Examination (abbreviated).—The patient was obese, the obesity being confined mainly to the trunk and face, the extremities being comparatively free. There were no abdominal striae, the skin was dry. There was considerable hypertrichosis, involving the cheeks, the upper and lower lip, the chin and the extremities, there was less hair growth on the abdomen and chest and there was virile distribution of hair. The breasts were small and atrophic. The external genitalia were of normal appearance, the clitoris was small, not hypertrophic. On rectal examination no mass was palpable, the internal genital organs were apparently normal. Physical examination otherwise revealed perfectly normal conditions. The blood pressure varied from 110 to 130 systolic, 70 diastolic.

Laboratory Examination.—The urine, blood count and blood chemistry were normal. X-ray plates of the skull (sella) and a pyelogram showed no pathologic condition. Eye examination and visual field determinations were normal. Quantitative titration of the urine for gonadotropic substance revealed its absence in amounts exceeding 66 mouse units per liter. The method used was Zondek's alcohol precipitation method.² Estrogenic substance was found very markedly increased. A positive Allen-Doisy smear was obtained with 2 cc. of urine in forty-eight hours, indicating the excretion of 5,000 mouse units per liter.

The diagnosis rested between Cushing's pituitary basophilism, adrenogenital syndrome, and arrhenoblastoma of the ovary. Because of the absence of the cardinal symptoms of Cushing's disease such as hypertension, hyperglycemia, hyperglobulia, osteoporosis, negative X-ray appearance of sella and negative eye observations, the possibility of either an adrenal cortex hyperplasia or tumor, or an arrhenoblastoma of the ovary was considered. Both conditions are known to give rise to the marked heterosexual changes; our case offered. Operation was suggested because of the continuous progression of symptoms and because of the possibility of an early malignant condition.

Operation (Dr. Parker).—July 21, a midline subumbilical incision was made. Exploration of the pelvis revealed a normally appearing uterus and normal tubes. The ovaries were of average size, the right somewhat larger than the left. In the right ovary three pin-head sized cysts were visible. The ovary was therefore removed. Palpation of both kidneys showed them to be of normal size and consistency. Both adrenal glands were examined carefully by palpation. No

Fig. 1.—Girdle obesity and hirsutism.

enlargements, swellings, tumors or cysts were detected. The appendix showed evidence of chronic inflammation and was removed. The abdomen was closed in layers without drainage.

Histologic Examination (Dr. Otto Saphir).—Sections of the ovary revealed multiple apparently degenerated primordial follicles in the peripheral portions of the cortex and in the deeper layers follicles in various stages of maturation. Multiple cystic spaces were noted. Some of these contained eosinophilic amorphous debris and were lined by granular cells. Others were empty, their lining undulated and apparently formed by a vascularized theca layer. Corpora albicantia were fairly numerous. In hyalized fibrous connective tissue at the periphery of one section was a circumscribed nest of cells that resembled the cortical cells of the adrenal. These cells had clear vacuolated or finely granular eosinophilic cytoplasm. Delicate chromatin granules were diffusely distributed throughout the oval nuclei, some of which contained one or two large

² Zondek, Bernhard. *Die Hormone des Ovarium und des Hypophysenvorderlappens*. Berlin: Julius Springer, 1931.

granules. The nuclear membranes were well defined the cytoplasmic membranes clear and the cells in immediate contact.

Course—The patient made an uneventful recovery. On the fourth day following the operation menstruation commenced. The regular menstrual cycle was resumed and has continued since (ten months). There was a slight reduction in weight but no marked improvement of the hypertrichosis up to date. The increased estrogenic excretion disappeared. Four weeks after the operation no vaginal cornification was obtained in castrated mice with the injection of as much as 6 cc of urine within 100 hours.

COMMENT

The cardinal symptoms of the case described were sudden onset of amenorrhea, gain in weight, and hirsutism. These symptoms may well be ascribed to either one of the three conditions: (1) adrenal cortex hyperactivity, whether a benign adenoma, hyperplasia, or a malignant hypernephroma, (2) Cushing's pituitary basophilism, (3) certain types of ovarian tumors called by Robert Meyer³ arrhenoblastoma.

As to adrenal cortex disorder, it is well to remember the embryologic origin of this tissue. It is derived from the coelomic epithelium of the urogenital fold, which in later embryonic life divides into adrenal cortex and gonads. Adrenal cortex, ovaries and testes, therefore, derive from a common ancestry. This fact may well explain the heterosexual changes so frequently found in the adrenal-genital syndrome. It also explains the presence of aberrant adrenal cortical tissue anywhere along the original preformed urogenital "anlage." Indeed, such tissue has been found by Kolodny⁴ in the retroperitoneal space in a typical case of adrenal virilism, by Marchand⁵ in the ligamentum latum, and by

apparent that partial or total adrenalectomy in such cases, as has been advocated, will be futile as long as the causative tumor or tissue responsible for the symptoms has not been removed.

The danger of such procedures has been pointed out in a recent editorial in THE JOURNAL.⁶ The fact that our patient did not lose her hirsutism after operation leaves the possibility open that additional aberrant

Fig 3—Section of ovary containing nests of clear cells morphologically similar to cells of the adrenal cortex.

adrenal cortex tissue may be present in other locations or that there may have been some unrecognized disease in the adrenals.

Our case, furthermore, offers points of interest as to the differential diagnosis of Cushing's syndrome of pituitary basophilism. Although obesity, amenorrhea and hirsutism are considered symptoms pertinent to Cushing's disease, other features such as hypertension, hyperglycemia, hyperglobulia, osteoporosis and purple abdominal striae were missing. A negative roentgenogram of the sella apparently can be evaluated as little as a negative pnelogram.

The marked excretion of estrogenic substance found in our patient seems to be an important sign in favor of adrenal cortex disturbance. This phenomenon, discovered by Frank,⁷ may best be explained again by the common embryologic origin of both adrenal cortex and gonads. It may well be conceivable that the cells of the adrenal cortex may retain the faculty of producing gonadal hormones under pathologic conditions.

Because of the rarity of these conditions, titration of body fluids for gonadal and for gonadotropic substance has not yet been adequately undertaken in Cushing's disease and arrhenoblastoma of the ovary. It is to be hoped that further work along these lines will be helpful in analyzing such and similar clinical pictures, which heretofore offered grave difficulties in their diagnosis.

us within the ovary itself. It becomes clear, therefore, that the presence of seemingly normal adrenal glands which were palpated during operation does not rule out the diagnosis of suprarenal virilism. It also becomes

SUMMARY AND CONCLUSIONS

1 Adrenal virilism is the clinical manifestation of hyperactivity of the adrenal cortex gland

2 In a case of adrenal virilism the adrenals appeared to be normal, but aberrant adrenal cortex tissue was found within the ovary

3 Increased function of adrenal cortex seems associated with increased excretion of estrogenic substance

4 The clinical and physiologic manifestations of adrenal virilism may be explained on the basis of the embryologic origin of adrenal cortex

THE TREATMENT OF LARGE PULMONARY ABSCESES

CLARENCE E. BIRD, M.D.
LOUISVILLE, KY

Four years ago my interest in the subject of large pulmonary abscesses was greatly stimulated when the question arose as to the advantages of draining a necrotic right upper lobe in the anterior axillary line instead of more posteriorly

CASE 1—A man, aged 32, a cook had been very ill with a rapidly progressing and destructive pneumonia. When first seen he was propped up in bed under an oxygen tent excited, dyspneic, pale perspiring and nauseated from the foul odor of sputum. Roentgenograms (fig 1) showed that the abscess was extensive, but fortunately the liquefying process had not perforated the oblique or horizontal fissures. In the semisitting position, in which the patient was most comfortable it was evident that drainage anteriorly would be most dependent. Under local anesthesia a section of the fifth rib was removed in the anterior axillary line and soft rubber tubes were placed on the indurated horizontal pleura. Within six weeks the discharge had ceased and the walls of the large cavity, when observed through a fore-oblique cystoscope were found to be granulating in a healthy manner, even far into the open bronchi. Removal of long segments of the first to the fifth ribs subperiosteally by a posterior approach resulted in obliteration of the space and rapid, complete and permanent healing of the sinus (fig 2). The patient remains well after four years.

Subsequently I have had the opportunity to treat twenty more patients with pulmonary abscesses by surgical methods. In order to present a well balanced picture of the disease as it occurred in the hospital as a whole, I have prepared a table to show the etiology of seventy cases admitted since July 1, 1932 (table 1). There were forty-six (65.7 per cent) in which the cause could not be ascribed to anything more definite than a "cold," "influenza" or "pneumonia." In twenty (28.6 per cent) the abscesses followed operations, infected traumatic wounds or other extrapulmonary infections. Two cases occurred after diabetic coma, one following alcoholic stupor, and another in a premature infant.

Table 2 shows the results in the seventy cases. Fourteen patients were too ill for treatment of any kind and died. Eleven left the hospital against advice one is well, eight are improved and two are unimproved. Eighteen were treated in the medical and pediatric services two are well eleven are improved and five are dead. Of my twenty-one personal patients, ten are well (no cough or sputum wounds soundly healed)

Because of limited space many of the illustrations shown by lantern slides at the meeting have been omitted.

From the Department of Surgery, Louisville City Hospital and the University of Louisville School of Medicine.

Read before the Section on Surgery General and Abdominal at the Eighty-Seventh Annual Session of the American Medical Association, Kansas City, Mo., May 15, 1934.

five are improved and six are dead. Six were treated in other surgical services three are improved and three are dead.

The causes of death in my personal cases were as follows: in two, multiple abscesses with progressive pulmonary gangrene, in one, virulent empyema complicating pneumothorax, which occurred at the second stage of a two-stage drainage, in one, virulent empyema complicating pneumothorax, which occurred at the first stage of a proposed two-stage drainage, in one, virulent empyema in an old man, which occurred at the time of a one-stage drainage and in one, hemolytic streptococcus septicemia, pericarditis and peritonitis following a two-stage lobectomy for chronic abscess.

As a result of these personal experiences good and bad, which parallel those described in the literature since the time of Murphy,¹ the following points in relation to the surgical treatment seem to me to be of the greatest importance:

1 Pulmonary tuberculosis, foreign body and tumor must be suspected in all cases and should be excluded by examinations of the sputum, bronchoscopy and biopsy of the pleura and lung.

2 Postural drainage should be avoided in patients who are very ill.²

3 Because of the danger of empyema, pyopneumothorax (with bronchopleural fistula and tension pneumothorax), hemorrhage into the cavity, cerebral air embolism, or abscess of the chest wall thoracostomy should not be done.

Fig. 1 (case 1).—Abscess of the right upper lobe drained through the fifth rib in the anterior axillary line. Thoracostomy by way of the fourth rib in the midclavicular line would have been preferable.

4 Patients with bronchopleural fistula and foul empyema secondary to lung abscess are more likely to recover with prompt open drainage than by repeated thoracostomy or catheter drainage with a water seal. In my experience, repeated aspirations have led to painful debilitating phlegmons of the thoracic wall while catheter drainage has been followed shortly by infection and leakage about the catheter. Violent shifts of intra-pleural pressure occur if the tube becomes temporarily occluded.

5 Treatment by pneumothorax is dangerous except when the abscess is definitely so far removed from the periphery that it cannot possibly rupture into the pleural cavity.

6 Patients should not be operated on as a rule while there is pain. The pain indicates pleural inflammation, frequently with extension of a pneumonic process. The operation will be safer later.

7 With very few exceptions, surgical treatment should not be instituted within six weeks after the onset of the disease.

1 Murphy, J. B. Surgery of the Lung. J. A. M. A. 31:231, 1918.
2 Bruhn, Harold. Lung Abscess. J. A. M. A. 103:197, 1934 (Dec. 29).

8 However, constant cough with nausea, anorexia and insomnia, accompanied as they are by rapid loss of weight and strength, may in themselves indicate the necessity for prompt surgical drainage³

9 In patients who fail to improve by nonsurgical therapy, surgical drainage should be carried out soon after the end of the six weeks period. Many complications are thus avoided and fibrosis and bronchiectasis are minimized.

Fig. 2 (case 1)—A limited extrapleural thoracoplasty performed nine weeks after the abscess was drained obliterated the cavity and closed the sinus.

10 Operations for pulmonary abscess should be conducted under local anesthesia.

11 Small abscesses should always be drained by the two-stage method, and many large abscesses should be opened in this manner. (In one of my cases a hemostat, carelessly placed, opened the normal pleura near an abscess that was adherent over only a small area. Pneumothorax, foul empyema and death resulted.)

12 Many of the larger abscesses should be drained by the two-stage method but when the pleural surfaces are involved over a wide area and the patient is very ill the preliminary stage should be dispensed with.

13 Drainage should be so planned that it will be dependent. This requires an accurate localization of the lowermost limits of the liquefaction and a knowledge of the confines of the lobes in relation to the thoracic wall.

14 The best and most permanent results are secured when dependent drainage is maintained under constant supervision, preferably in the hospital until the cavity is entirely healed. Excessive fibrosis, bronchiectasis, chronicity and recurrence are thus avoided.

In fifteen of my twenty-one cases, more than half of one or more lobes was involved. For my purposes in this paper, destruction of this extent defines roughly the large pulmonary abscesses.

The matter of long continued dependent drainage for large abscesses is of such importance that I have chosen to utilize most of my time to emphasize the point. Even with small abscesses of the right upper lobe, an anterior approach is the only logical one (fig. 3A). Posterior drainage is difficult and ineffective for this lobe. Midaxillary drainage, unless placed high, requires the traversing of a portion of the uninvolved lower

lobe and the interlobar pleura and increases the length of the drainage tract. Furthermore, drainage by that route often does not permit the opening of the lowermost portion of the lobe. The sites of drainage that are recommended for right upper lobes of the usual size are the fourth or fifth ribs in the anterior axillary line or the third or fourth ribs in the midclavicular line. When the lobe is very small, drainage should be made occasionally as high as the second rib in the midclavicular line. Wherever the horizontal interlobar pleura may lie, an accurate determination of the posi-

tion and direction of its slope can usually be made by fluoroscopy and x-ray examination. Of course it is not uncommon for an abscess to perforate the interlobar pleura. Drainage must then be made through the ribs that overlie the most dependent portion of the involvement. Thus an upper lobe abscess may be drained through the lower lobe.

Experiences with large abscesses in the left upper lobe have convinced me that there also the anterior route is correct. The following case describes the troublesome course of a patient in whom the usual midaxillary approach was utilized.

CASE 2—A stableman aged 40, came to me in a precarious condition three weeks after the onset of pneumonia. Stereoscopic films of the chest showed multilocular abscess cavities with fluid levels in the upper portion of the left root area and in the left upper lobe extending to the periphery (fig. 4). Three centimeters of the fifth rib was removed in the mid-axillary line. This route of drainage led through an inflammatory zone in the upper lateral portion of the left lower lobe and forced traversing the thickened oblique pleura before entering the cavity of the abscess. The fever and expectoration

Fig. 3—A the sites suitable for the drainage of most abscesses of the right upper lobe are shown by the ribs numbered in the anterior axillary and midclavicular lines. B drainage of the left upper lobe should begin at the third rib in the midclavicular line. C the sites for opening the middle lobe are the fifth and sixth ribs lateral to the costochondral junction.

subsidized but the drainage was incomplete. Furthermore, the patient had been subjected to the possibility of an acute empyema in the lower portion of the thorax. Thereafter it was necessary to drain anteriorly through the second third and fourth ribs in the midclavicular line and to carry out an extensive multistage thoracoplasty in order to cure the patient (figs. 5 and 6). The entire treatment extended over a period of eight months.

In striking contrast to the long hazardous convalescence in the case just discussed was the short and uncomplicated recovery in case 3

CASE 3—A mill operator, aged 28, had extensive destruction of the left upper lobe resulting from pneumonia. A lateral film showed the process confined to the left upper lobe and suggested the appropriateness of anterior drainage. This was carried out by excising a segment of the third rib in the mid-

Fig. 4 (case 2)—A multilocular abscess in the left upper lobe. The lobe is destroyed almost completely. The black dot lies over the fifth rib in the midaxillary line where drainage was established improperly

little iodized oil entered the bronchial tree. The sinus closed promptly six and one-half weeks following the thoracostomy

The site of primary drainage that is recommended for these large abscesses of the left upper lobe is the third rib in the midclavicular line (fig 3B). The third rib is chosen rather than the fourth or fifth, because it lies over a safe zone well away from the pericardium. Having once entered the lung, if the process extends lower, one can remove segments of the fourth, fifth or even sixth or seventh ribs under guidance of the finger in order to drain the lingual portion of the lobe.

The middle lobe is not often affected except in conjunction with the upper or lower lobes and in abscesses at the root of the lung. The proper approach is through the fifth or sixth ribs lateral to the costochondral junction (fig 3C). This route avoids the pericardium and prevents chondritis. Carried more deeply, the approach provides excellent drainage for abscesses at the right root.

For the lower lobes (fig 7A), with the patient in a position approaching the upright and turned somewhat toward the affected side, dependent drainage is obtained by thoracostomy anywhere along the lowermost borders. Thus, on either the right or the left side if the liquefaction is shown by physical examination, fluoroscopy and films to be greatest posteriorly, portions of the tenth and eleventh ribs are removed over the paravertebral gutter, or less often a segment of the tenth rib is excised below the angle of the scapula. If the liquefaction is most extensive laterally or anteriorly, the proper sites of drainage for the left lower lobe are through the bed of the ninth rib in the midaxillary line (fig 7B), the eighth rib in the anterior axillary line or the seventh or sixth ribs still more anteriorly in the midclavicular line. On the right side (fig 7C), because of the interposition of the middle lobe drainage of the most anterior portion of the lower lobe is carried out as a rule, through the bed of the ninth rib in the mid-

axillary line or the eighth rib in the anterior axillary line. But for the lower lobes, as for the upper there are large individual and age variations in the relationship of the ribs to the lobes, so that in each case the proper ribs for excision must be determined by fluoroscopy and x-ray examination in order to obtain the best dependent drainage.

If drainage is established at these dependent portions of the lower lobes, healing will usually occur eventually without thoracoplasty even when there is extensive destruction of pulmonary tissue. The structure particularly the diaphragm and the heart are more mobile than those surrounding the upper lobes and tend to obliterate the dead space, so that thoracoplasties over the lower lobes are necessary less often than over the upper lobes.

CASE 4—In a grocery clerk, aged 36, whose abscess complicated bilateral bronchopneumonia, closure of a large abscess occurred without a thoracoplasty. Three centimeters of the right ninth and tenth ribs were resected below the angle of the scapula. The thickened pleura and a thin shell of consolidated lung were traversed and the offensive pus and necrotic pulmonary tissue were removed directly above the diaphragm. After the patient had regained his strength, the right phrenic nerve was crushed. Repeated observations of the cavity by the cystoscope through the sinus tract showed the casting off of the sloughing masses, the gradual expansion of the remain-

Fig. 5 (case 2)—The patient eight months later subsequently to effective anterior drainage and an extensive thoracoplasty

ing pulmonary tissue the rise of the diaphragm the formation of clean granulations and the contracture of scar tissue which pulled the parietal and visceral walls of the cavity together gradually. Iodized oil injected into the sinus tract seven weeks after operation showed reduction in the size of the cavity and two or three remaining communications with the bronchial tree. Thereafter the space closed progressively and healing was complete and permanent six weeks later. A roentgenogram taken one year after operation showed the diaphragm fixed at a high level.

CASE 5—However, in a girl, aged 17, whose infection caused gangrene in an atelectatic, pneumonic left lower lobe obliteration of the cavity failed to occur. Dependent drainage was obtained by the removal of a segment of the tenth rib below the angle of the scapula. The convalescence was extremely hazardous and the foul discharge from the sloughing surfaces did not cease entirely for three months. The result was a firmly fixed, fibrosed lung, perforated by many open bronchial fistulas. The diaphragm and pericardium were immobilized

Fig 6 (case 2)—The obliterated left upper lobe

by scar tissue. The size and situation of the cavity and the communications with the bronchial tree were demonstrated in films made after the injection of iodized oil. There seemed to be no possibility that nature would close this space within a reasonable time. When observations through a cystoscope showed the tissues to be healthy, a regional thoracoplasty was performed in which segments of the sixth to the ninth rib 11 cm long were excised thus collapsing the roof. The sinus closed immediately and a film taken sixteen months later showed only fibrosis and regenerated ribs. This patient remains well three years after her illness.

CASE 6—A Negress, aged 36, did not do as well because, I think, the large posterior abscess of the left lower lobe was drained at too high a level. The sites of drainage were those recommended, but the diaphragm was exceptionally low and this feature was not taken sufficiently into account. The history suggested a complication of pneumonia which she had had two months previously. Bronchoscopy showed no foreign body. A segment of the tenth rib was excised below the angle of the scapula. Multilocular cavities in a dense atelectatic lung were found and drained, leaving large wide open bronchial fistulas. At a second operation one month later the wound was enlarged and the vertebral portions of the tenth and eleventh ribs were removed. Still the diaphragm had not been reached. Three months later the patient continued to raise a moderate amount of sputum, and the honeycombed lung was actively suppurating. A long segment of the ninth rib was resected to provide wide exposure, and a large mass of the consolidated chronically infected lung was removed with the endotherm. At the same time the diaphragm was paralyzed. The suppuration continued and from this time on the patient refused further operations. I have followed her with interest for the ten months since that time. After four months the output of sputum decreased to zero and she began to gain weight and strength. However, she has continued to require daily dressings. The cavity extends upward paravertebrally for about 6 cm. Everywhere above the diaphragmatic portion it is perfectly free from suppuration but with each cough pus exudes from the lowermost bronchi. In order to effect a cure it will be necessary to remove the remaining rim of suppurating lung which lies against the diaphragm below the level of the wound.

When there is pneumonitis surrounding an abscess, the limits of the disease are often difficult to determine, but by draining dependently within the limits of pleural involvement, provision is made for the liquefaction of portions of the lung that may not as yet be definitely involved. When open drainage is made for a small abscess the site of the operation must be determined to a great extent by the position of the lesion but it is frequently possible to place the opening near one of the sites of drainage that are preferable for large abscesses.

As a rule, abscesses at the root of the lung which do not involve any one lobe and which require open drainage are best approached either anteriorly or posteriorly low in the chest by two-stage drainage. However, a large chronic abscess centrally placed but involving definitely a single lobe may be treated by lobectomy without preliminary external drainage. This plan of treatment was followed in case 7.

CASE 7—A Negro girl aged 22, had a postpneumonic, centrally placed abscess of the right lower lobe of one year's duration which failed to respond to treatment by bronchoscopic aspiration, pneumothorax and paralysis of the diaphragm. Following a preliminary pneumolysis and the production of adhesions over the upper and middle lobes, the lower lobe was removed by dissection. A film taken four months later showed that the heart, diaphragm and other lobes had obliterated the dead space.

SUMMARY

Attention has been directed to fourteen points that I consider to be of the greatest importance in relation to the surgical treatment of pulmonary abscesses.

Emphasis is placed on long continued, dependent drainage, under hospital care, until the cavity of the abscess is entirely obliterated. Fibrosis, bronchiectasis, chronicity and recurrences are thus avoided. During these periods of hospitalization it is interesting and instructive to observe the healing cavities repeatedly through an ordinary fore-oblique cystoscope passed through the wound of operation.

For most cases the ideal sites of drainage for large abscesses are, for the right upper lobe, the third or fourth rib in the midclavicular line, for the middle lobe, the fifth or sixth rib lateral to the costochondral junction, for the left upper lobe, the third rib in the midclavicular line lateral to the pericardium, with removal of lower ribs under direct guidance of the finger if necessary, for the lower lobes posteriorly and laterally, the tenth and eleventh ribs over the paravertebral gutter, or the tenth rib below the angle of the scapula or the ninth rib in the midaxillary line, for the left lower lobe anteriorly, the eighth rib in the

Fig 7—A large abscesses, which are placed posteriorly in the lower lobes, are drained through the tenth and eleventh ribs over the paravertebral gutter occasionally even lower. B when the greatest destruction is in the lateral or anterior portion of the left lower lobe thoracostomy is established through the ninth, eighth, seventh or sixth ribs between the midaxillary and midclavicular lines. C on the right side large abscesses of the lower lobe that involve the lateral and anterior portions are drained through the ninth rib in the midaxillary line or the eighth rib in the anterior axillary line.

anterior axillary line or the seventh and sixth ribs in the midclavicular line, for the right lower lobe anteriorly, the eighth rib in the anterior axillary line. There are individual and age variations, and elevation of the diaphragm due to atelectasis and fibrosis must be taken into consideration when the site of drainage for chronic abscesses is chosen.

Among my twenty-one patients with pulmonary abscess treated surgically during the past four years, ten are well, five are improved and six are dead. This mortality rate of 28.6 per cent should be improved.

ABSTRACT OF DISCUSSION

DR. ALFRED BLALOCK, Nashville, Tenn. It is important to realize that there are marked variations in the clinical course and in the pathologic changes caused by lung abscesses. Some patients recover spontaneously; others do not respond favorably to any treatment. Each case is a problem in itself. One of the most important points connected with the treatment of a lung abscess consists in determining when the more conservative methods should be abandoned and when surgical drainage should be used. The trend at the present time appears to be toward earlier operation. This has the advantage of lessening the likelihood of the development of bronchiectasis and of the late complications associated with abscesses. On the other hand, if one operates too early, one is forced to open through an area of edematous lung with poor resistance to infection. This is likely to result in an extension of the infection. Operation should be postponed until there is a well developed delimiting pyogenic membrane. In general, it is better to wait at least six weeks following the onset before attempting drainage and it is probably wiser to extend this period to three months. The two important points in the operative technic are dependent drainage and the entrance into the cavity with as little damage to normal pulmonary tissue as possible. Dr. Bird has pointed out that there are large individual and age variations in the relationships of the ribs to the lobes and that in each case the proper ribs to be resected should be determined by fluoroscopy and x-ray examinations. It is generally stated that it is important to determine if possible whether or not there are adhesions between the two pleural surfaces at the proposed site of drainage. This has probably been overemphasized, since it is usually safer, even in the presence of adhesions, to perform the drainage in two stages. Extremely important is an ample opening in the chest wall so as to avoid working in the dark and so that the entire superficial area of the abscess may be within reach. If it is found that the incision is not ideally located for drainage, it should be enlarged at once. If heavy muscles overlie the cavity, they should be divided at right angles. At least one and usually several ribs including the periosteum should be resected. The cavity should be as completely deroofed as seems feasible, with an attempt always to have the external part of the opening larger than the more internal portion. The drainage of pulmonary infections differs from that of abscess in most parts of the body in the desirability for free access to the entire cavity in order that possible bleeding points may be visualized and connections with neighboring pockets of pus may be enlarged. One of the distressing complications that I have encountered far too frequently is air embolism. Usually this has not resulted fatally. With further improvements in the technic of lobectomy, it is entirely possible that this procedure will largely replace that of surgical drainage.

DR. PETER B. SALATICH, New Orleans. All know how dangerous these abscesses of the lung are. I had some experience especially during the influenza epidemic with the use of vaccines. The effect is gratifying, not so much in large abscesses but in smaller ones. I do not mean the use of vaccine as recommended by the manufacturers in small doses. I commence the treatment with 0.25 cc. and rapidly increase the dose. The next day I give 0.5 cc. If no reaction takes place I give 1 cc., then 2 cc. and up to 5 cc. When 5 cc. is reached I repeat the dose every second or third day. I have had the opportunity of observing these cases with the x-ray, every two or three days and I find that these abscesses disappear under the vaccine therapy with no other form of treatment.

DR. CLARENCE E. BIRD, Louisville, Ky. I have had no experience in the use of vaccines in the treatment of pulmonary abscesses and am unable to comment on the advisability of their use. I should judge, however, that the use of vaccines would be one of those measures which might be tried together with bronchoscopic drainage, adequate bed rest and other types of careful medical treatment for a period, until it is found that the patient either does or does not improve.

RÔLE OF SYPHILIS OF THE NERVOUS SYSTEM IN THE PRODUCTION OF MENTAL DISEASE

A SURVEY OF THE VARIOUS FORMS OF NEURO-SYPHILIS OCCURRING AT THE BOSTON PSYCHOPATHIC HOSPITAL FROM 1912 TO 1934

MERRILL MOORE, M.D.

AND

H. HOUSTON MERRITT, M.D.

BOSTON

Accurate statements with regard to the role of syphilis in the production of mental disease are rare in medical literature. The figures cited by Krapelin and Lange¹ refer only to dementia paralytica and were collected mainly in the days before the common use of the Wassermann reaction. For this reason it has been thought advisable to survey the records of all admissions to the Boston Psychopathic Hospital since its opening in June 1912 in order to determine what role syphilis played in the production of mental disorder among patients observed there. The records of the Boston Psychopathic Hospital are particularly suited for such analysis because this hospital is an important and active center for diagnosis and the material that passes through it represents a cross section of mental diseases as they occur in the community at large. In addition there is relatively little selection in the patients

TABLE 1—Correction of Original Figure of Admissions

Total admissions for years 1912 to 1934	40,848
Less readmissions (10.3% of 40,848)	7,849
Total first admissions	32,999
Less those diagnosed without psychosis	6,227
Total first admissions with psychosis	26,772

* 10.8 per cent of 32,999

who are brought there for observation and for the great majority of them admission to the Boston Psychopathic Hospital constitutes the first hospitalization in the course of their mental disturbance.

The total admissions to the Boston Psychopathic Hospital from June 24, 1912, to August 1, 1934, were 40,848. An analysis of the hospital's diagnosis files showed that 2,832 of these 40,848 were found to be suffering from some form of syphilis of the nervous system. This figure represents 2,832 different patients, since each of them was analyzed individually and all readmissions were excluded. The diagnosis in these 2,832 patients was based on the observations on neurologic examination in conjunction with the results of examination of the cerebrospinal fluid obtained by lumbar puncture. Since lumbar puncture is not performed as a routine in every case admitted, and since it is well known that active syphilis of the central nervous system can exist and produce mental symptoms without objective signs on neurologic examination, there are undoubtedly a certain number of cases in which a syphilitic infection of the central nervous system was present but not detected.

In determining the role of syphilis as a cause of mental disease it was necessary to determine the actual

We are indebted to Mr. Sidney Levin for assistance in the preparation of this material.
From the Department of Diseases of the Nervous System, Harvard Medical School, the Boston Psychopathic Hospital and the Neurologic Unit of the Boston City Hospital.
¹ Krapelin, E. and Lange, J. *Psychiatric Leipzig Jahrbuch* 1922.

number of patients admitted to the Boston Psychopathic Hospital with a diagnosis of mental disease. In order to arrive at this figure it was necessary to exclude from the 40,848 admissions all readmissions as well as all patients who were diagnosed as "without psychosis." Similarly, it was necessary to exclude from the 2,832 patients with neurosyphilis those who were diagnosed as "without psychosis" and those in whom the psychosis was considered to be unrelated to the syphilitic infection of the nervous system.

TABLE 2—Classification of the 364 Patients with Neurosyphilis in Whom Syphilis of the Nervous System Did Not Produce 'Mental Disease' *

Type of Mental Disorder	Tabes Dorsalis	Meningo vascular Neurosyphilis	Undifferentiated Types of Neurosyphilis	Totals
Symptomatic psychoses	0	2	0	8
Psychoses due to organic brain disease other than neurosyphilis	2	2	5	0
Psychoses due to exogenous toxins	0	0	1	1
Affective psychoses	0	0	4	4
Schizophrenic psychoses	0	2	7	0
Conditions of mental defect	0	3	10	13
Conditions of mental instability	1	2	6	9
Without psychosis	72	101	138	311
Totals	75	112	177	364

* The sex distribution in this group of cases of neurosyphilis is as follows: 237 or 65 per cent male* and 127 or 35 per cent females.

It was not possible to arrive at an absolutely accurate figure with regard to the corrections for the total admissions for the entire period of this study, since statistics are obtainable only since 1928.² For the seven year period 1928 to 1934, readmissions constituted 19.3 per cent of the total admissions. Patients diagnosed "without psychosis" constituted 19.8 per cent of the first admissions. We are of the opinion that the figures for these seven years give a fairly representative picture and can be used for the entire period of this study. The result of correction of the original figure of 40,848 for these two factors is given in table 1.

The diagnosis of syphilis of the central nervous system was made in 2,832 of these patients, subdivided as follows: dementia paralytica, 2,251 patients; meningovascular neurosyphilis, 250, undifferentiated

The 2,468 patients in whom the syphilitic infection of the nervous system was the cause of their psychosis were divided as in table 3.

Table 3 shows that dementia paralytica and the tabetic form of dementia paralytica constitute by far the great majority (approximately 94 per cent) of the patients with mental disease due to neurosyphilis and that other forms of neurosyphilis played a very minor rôle in the production of mental disease.

Therefore, if 26,437 represents the actual number of first admissions of psychotic patients and 2,468 the number in whom syphilis of the nervous system was the cause of the psychosis, then syphilis of the nervous system is found to be the cause of the mental disease in 9.3 per cent.

SUMMARY

1 Syphilis of the central nervous system was considered as the cause of the mental disease in 2,468 patients admitted to the Boston Psychopathic Hospital in the first twenty-two years of its existence—from 1912 to 1934.

2 When corrections are made in the total admissions for the number of patients who were found to be "not psychotic" and for the number of readmissions, syphilis of the nervous system was considered the cause of mental disease in 9.3 per cent of the total.

3 Dementia paralytica and the tabetic form of dementia paralytica constituted 94 per cent of the 2,468 cases of mental disease due to syphilis of the central nervous system.

INTERNAL HERNIA FOLLOWING ROUND LIGAMENT SUSPENSION

REPORT OF TWO CASES

M. A. MICHAEL, MD
PHILADELPHIA

In describing the ventral suspension operation for retroversion such as the Gilliam, Olshausen or the Graves modification of the latter, Graves,¹ Crossan² and Miller³ all call attention to the danger of intestinal obstruction from internal herniation following this type of suspension but feel that the occurrence of this sequel is exaggerated. In the original Gilliam operation the round ligaments are brought by a perforating clamp through the peritoneum, muscle and fascia and fastened to the outer side of the fascia. In the Simpson modification of the Gilliam operation the round ligaments are brought through the peritoneum to the internal ring and make intestinal complications less likely. In either the Gilliam or the Olshausen operation there is created a potential hernial ring between the point of attachment of the round ligament to the peritoneum and its exit by way of the internal ring to the inguinal canal. Under this arch a loop of intestine can easily fall and become obstructed. Crossan suggests avoiding this complication by using the puckering suture of Ferguson to obliterate the space created between the distal portion of the round ligament and the abdominal wall.

In searching the literature on intestinal obstruction following round ligament suspension, one finds that

Philadelphia W B Saunders Company 1928
2 Crossan A S Operative Gynecology St. Louis C V Mosby Company 1920
3 Miller C J Retrodysplacements in Davis C H Gynecology and Obstetrics Vol 11 831

TABLE 3—Cause of Psychosis in 2,468 Patients

	Patients	Per Cent
Dementia paralytica	2,251	91.2
Tabetic form of dementia paralytica	66	2.7
Meningovascular neurosyphilis	138	5.6
Undifferentiated neurosyphilis	13	0.5
	2,468	100.0

types of neurosyphilis, 190, tabes dorsalis, seventy-five, and the tabetic form of dementia paralytica, sixty-six.

It is necessary now to exclude from these 2,832 patients with neurosyphilis 311 who were diagnosed as "without psychosis" and fifty-three in whom the psychosis was considered to be unrelated to the syphilitic infection of the nervous system, giving a total of 364 patients, as shown in table 2. When the 364 (table 2) are excluded from the 2,832 patients with neurosyphilis, there remain 2,468 in whom the syphilitic infection of the nervous system was considered as the primary etiologic factor in the production of the mental disease.

2 These figures are furnished by Dr. Neil A. Dayton, director of the Division of Statistics and Research Department of Mental Diseases, Commonwealth of Massachusetts.

there is a sparsity of reports, this might be due to the fact either that the condition occurs infrequently or that it has not been always reported. Though cases of internal hernia are not uncommon, here one is usually dealing with herniation into one of the various intra-abdominal fossae. McIver⁴ studied the cases of acute intestinal obstruction occurring at the Massachusetts General Hospital from 1918 to 1927 and out of forty-five cases of late postoperative obstruction eight followed pelvic operations, but the type of operation was not mentioned. In a larger series of cases McIver⁵ found internal hernia to comprise only 0.9 per cent of 335 cases.

In 1924 Pidcock⁶ reported a case of intestinal obstruction in which the round ligament acted as the obstructing band but there was no previous operative procedure, the patient was about fourteen days post partum.

Petersen⁷ of Denmark reported one case similar to those to be reported here, following anterior round ligament suspension of the Gilliam type. In Petersen's case a loop of small intestine was caught between the left round ligament and the uterus. Resection of the bowel was necessary and the patient made an uneventful recovery. Among 256 such suspension operations in Denmark from 1920 to 1925, Petersen found that two cases of obstruction had occurred. He recommended the Webster type of operation as a safer procedure.

However, Pemberton and Sager⁸ reported two cases in 1929 following the Webster-Baldy type of suspension for retroversion. In these cases the herniation was through the aperture created in the broad ligament through which the round ligaments are introduced. Webster in his original description mentions this as a possibility and recommends suturing these openings in the broad ligament to the round ligament.

Searle⁹ reported a case of obstruction following a ventral fixation operation (not round ligament suspension), in which the uterus was sutured to the anterior abdominal wall.

Many cases of herniation through abnormal openings or fenestrae in the broad ligament have been reported, but the round ligament was not a factor in any of these cases.

Two cases of intestinal obstruction following round ligament suspension have occurred in the service of Dr. F. B. Block at the Jewish Hospital during the past year and will now be reported.

REPORT OF CASES

CASE 1—A C., a white woman, aged 38, well developed and well nourished, admitted to the Jewish Hospital Nov. 16, 1934, complained chiefly of abdominal pain. Four days before admission there was soreness of the abdomen, the bowel movements were normal until the day before admission, when she had her last bowel movement. On this day she experienced acute pain in the abdomen generalized at first then more pronounced in the lower right quadrant. She was nauseated but did not vomit. The pain increased the next day, nausea and vomiting also occurred. The patient stated that she was well until a year

before, when she had an attack similar to the present one but it passed off in a few days. Five years before admission she had a uterine suspension operation. On admission her temperature was 98.2 F., pulse 70. On physical examination the patient was well nourished and complained of acute abdominal pain. No jaundice was present. Examination of the head, neck and chest was negative. The abdomen was flat and soft, no masses were palpable. Tenderness was present in the right lower quadrant and to a lesser degree in the left lower quadrant. The blood pressure was 120 systolic, 70 diastolic. The blood count revealed white blood cells 24,000, polymorphonuclears 90 per cent and lymphocytes 10 per cent. The urine was alkaline, with a specific gravity of 1.024, albumin was 4 plus with the acetic acid test. A flat x-ray film of the abdomen gave evidence of intestinal obstruction.

Under spinal anesthesia through a midline incision the abdomen was opened, a collapsed terminal ileum and distended jejunum were found. In the pelvis a knuckle of ileum was strangulated within the space created by the terminal portion of the broad ligament, the anterior abdominal wall and the left surface of the uterus (suspension operation site). The herniated bowel was freed, and the vessels leading to the ileum were found to be thrombosed, about 10 inches of gangrenous bowel was resected, and an end-to-end anastomosis was performed. Then an ileostomy proximal to the anastomosis was made and a No. 14 French catheter inserted. With the exception of a phlebitis of the left leg the patient made a fairly normal recovery and was discharged from the hospital December 7, twenty days after her operation.

Although not relevant to the present report, the patient returned to the hospital two days later with signs of intestinal obstruction, she was operated on and a loop of bowel was found adherent to the line of the former incision and obstructed. A lateral anastomosis was done around the obstruction, the loop being left in place. The patient left the hospital in two weeks and has been in good health since.

CASE 2—T. C., an Italian woman, aged 42, admitted to the service of Dr. Block, Oct. 27, 1935, complained of severe abdominal pain beginning at noon on the day of admission. She had been vomiting since the onset and seemed prostrated. Past medical history revealed that the patient had been until recently under treatment for syphilis. She had had an abdominal operation three years previously. On admission the physical examination showed temperature 97.3 F., pulse 88, blood pressure 170 systolic, 94 diastolic. Examination was essentially negative except for the abdomen, which showed tenderness in the left lower quadrant, peristalsis was practically normal. Under ether anesthesia through a midline incision the abdomen was opened and about 18 inches of dark red distended bowel was seen, a portion of which was locked between the right round ligament and the abdominal wall, resulting from a previous fixation operation. The round ligament was cut and each end ligated thus releasing the bowel, the color and tone of the latter having returned to a fairly normal condition, it was replaced and the abdomen closed. The patient made a normal recovery and was discharged November 11, thirteen days after operation.

SUMMARY

Many cases of internal hernia through the broad ligament, either postoperatively after the Webster-Baldy type of suspension or through fenestrae, have been reported.

Only three other cases of internal hernia following a round ligament suspension of the Gilliam type have been found reported in the literature, although the occurrence seems such a likely one.

Two cases of internal hernia following ventral round ligament suspension were seen in the service of Dr. Block. As a method of prevention when this type of suspension is done, it is the routine in Dr. Block's service that the space between the distal portion of the round ligament and the abdominal wall be obliterated by suturing these two structures together.

FIBROSITIS

W S C COPEMAN, M.D., M.R.C.P

Honorary Secretary Committee on Chronic Rheumatic Diseases
of Royal College of Physicians
LONDON

Much of the medical activity of the present generation, more particularly I believe in America, has been occupied in discovering how to estimate numerically the results of scientific research, and in finding out what type of measurement it is profitable to make. In most branches of medicine centuries of accurate observation have brought the subject up to the point where numerical description has become fruitful.

The scientific study of the chronic rheumatic diseases however has not passed beyond the stage at which the work of a Linnaeus would be a fresh landmark. In the realms of our knowledge of etiology much soil is virgin. The real credentials of medical science however lie in its capacity to yield information which is a guide to prevention or to practical treatment, and such being the case the empirical investigation of theories and therapeutic agents must also be granted a legitimate place in this, and indeed in any, branch of medicine until such time as it shall with truth be described as an exact science. Fibrositis is the term given by Sir William Gowers, toward the end of the last century, to an inflammatory reaction of fibrous supporting tissue to extraneous poisons either toxic or bacterial. Stockman and Renton later described the typical lesion: nodular or bandlike thickenings in the affected fibrous tissue, in the fascia lining the muscles or joints, or sometimes embedded in the substance of the muscles themselves. In the latter case they can only be felt when the muscles are in a state of relaxation after the passing of the acute attack.

Fibrositis may attack fibrous tissue wherever it is situated, and since such tissue may occur almost anywhere in the body the manifestations of this disease are protean. Roughly the situations in which it occurs with frequency may be thus classified:

1 Subcutaneous tissue—"panniculitis"—which will include the areolar and adipose tissue found in this situation. It will be seen in such cases that the skin loses its resilience and gets tied down to the connective tissue, dimpling like an orange skin when pinched. "Chilliness," a loss of tactile sensibility, a diminished response to faradic stimulation and suppression of sweating may also be found in this condition. Fatty tumors may sometimes form but are, as Stockman pointed out, only incidental to the main morbid process.

2 Intramuscular, which will include inflammation of the tissue that separates the fascial muscular planes ("myositis"), the lining of the bursae ("bursitis"), and the periarticular fibrous tissue ("capsulitis").

3 The fibrous sheaths of the chief nerve trunks, such as the sciatic or the brachial nerves ("interstitial neuritis").

Fibrositis in all these situations will be characterized by pain and limitation of movement, the pain being principally localized to the structures involved. Deformity will seldom result as is usual in the articular types of disease. Fibrositis is commonest in sites in which a combination of strain and chill occur most usually. This will tend to be in sites which are fairly superficial and where muscular planes merge into tendons or aponeuroses, since these portions of any

muscle both have a poorer blood supply and are less "elastic" than the more fleshy portions. Common situations are therefore the lumbar region (lumbago), the back of the neck, the shoulder, the scalp ("rheumatic headaches") and the elbow (certain forms of "tennis elbow"). Less common sites which will when affected often give rise to mistaken diagnosis are the attachment of the iliocostalis muscle to the lower six ribs, and the subcutaneous tissue of the precordial area. I have on several occasions been able to reverse a diagnosis of morbus cordis by discovering small tender nodules in this situation from which the pain has been found to radiate.

The pathology of the condition is necessarily somewhat vague, since the majority of sufferers will not consent to a biopsy of their nodules. A few examinations of this sort are however on record. The nodule, although typical of this condition from a clinical point of view, shows no typical pathologic structure. It is with difficulty dissected out, and when this has been accomplished the report of a histologic examination will generally be to the effect that inflamed scar tissue or "unhealthy" fibrous tissue, with no characteristic plan, is to be seen. Poynton also reported perivascular fibrosis. Their structure has not therefore the same appearance as that of the Aschoff nodules of acute rheumatism. The fibrous areolar tissue carries blood vessels and lymphatics to parts which are more functionally active but has itself a very limited blood supply. The result of this is that the lymphatics, being anatomically vulnerable to pressure, get considerably occluded during the process of scarring after the acute period is passed. The nutrient blood vessels are less vulnerable but can in most cases be seen to be thickened, while interstitial changes are also to be found in the nerve twigs locally. The modern tendency is thus to separate them entirely from the nodules of acute rheumatic fever. Whatever the actual etiology of fibrositis may be, the background will nearly always be found to reveal chronic fatigue or strain.

Clinically there appear to be two stages in most cases of fibrositis. 1 The stage of effusion, which may perhaps be likened to an internal form of urticaria. Where this is fairly superficial, a puffy swelling may be seen. 2 The stage of organization, during which the sero-fibrinous exudate gets partially absorbed, while the residue becomes invaded by fibroblasts, and a low grade fibrosis results forming intramuscular and interfascial adhesions and, later, palpable nodules. These nodules are not invariably painful to the touch unless a nerve twig is implicated, but it is noticeable that the severity of any case of (say) lumbago depends on the number and the extent of the nodules present, so far that the liability to relapse and to exacerbation is apparently directly proportional to these factors.

In addition to the pain associated with fibrositis, a further frequent complaint is of muscular stiffness, which generally persists even after the pain has disappeared. This stiffness is difficult to explain but is accounted for by some authorities as being due to the muscular hypertonus, which can be seen to exist in all acute cases. The muscles are unable to relax swiftly and completely and so the products of fatigue accumulate and the "habit" will persist even after the causative pain has been eliminated. Other authorities maintain that the cause is intramuscular adhesions, resulting from the period of exudation, which have to be stretched or absorbed before the affected muscles can resume normal function. Still other observers maintain

that this stiffness results from compression of the lymphatics, and so stasis in the muscular lymphatic drainage system

The most common forms of fibrositis are named according to their anatomic site, lumbago being perhaps the most typical form. "Sciatica" may also be of fibrositic origin, although this form should always be distinguishable from a true sciatic neuritis. Among the points of distinction between the two types may be mentioned that when the fibrositic form is at fault the pain is referred to the hamstring muscles and not to the nerve trunk (which is not even tender until later). There will be no anesthesia or paresthesias in the area of the distribution of the nerve, and the ankle jerk will not be affected. The pain is less lancinating and radiating, the subjective sensation being rather one of local soreness, tenseness and muscular stiffness, which is aggravated by muscular action. Finally, if muscular relaxation can be obtained, but not otherwise, nodules will be detected.

The causation of fibrositis is still a matter for dispute. It would seem clear however that it either results directly from bacterial invasion of the tissues locally (toxic focus) or else is the result of the sensitization of the fibrous tissues to some group of toxins, which may be either of bacterial or metabolic origin ("allergy"). The bulk of the evidence suggests that the latter explanation is in the majority of cases the more correct one. It seems moreover that in this case the toxins are probably of a protein nature. If this explanation is the correct one it will clarify the traditional association between fibrositis and gout as well as the seasonal incidence, which has been noticed by Thompson and Gordon and others in fibrositis.

The late L. J. Llewellyn believed that the origins of fibrositis were intimately connected with a preexisting subthyroid state. He pointed out that in hypothyroidism the first symptoms were those of vasomotor and vasosecretor instability, for example, cold extremities, poor circulation, erratic sweating and often actual Raynaud phenomena. He stated moreover that in the majority of his cases he had confirmed the presence of either enlarged or shrunken thyroid glands. An association between most forms of rheumatic diseases and thyroid disorders earlier in life is certainly common in my experience, but careful control work will be necessary before this can be regarded as more than an occasional or contributing factor in this disease group. Ray suggested that in those cases in which direct focal infection is apparently causative the upper respiratory tract and teeth will account for localization of the disease to the upper portion of the body, while where the lower limbs and trunk are affected the causative factor may be found in the bowel. Stockman has also pointed out the frequent association between mucomembranous colitis and fibrositis.

It has been said in the past by those who object to the theory of allergic sensitization that if this should be the case it would be difficult to account for the selective action of the inflammation for fibrous tissue. It has long been realized however that the selection of specific tissue is actually a characteristic of a large number of diseases now believed to fall into this category.

TREATMENT

For the purposes of treatment, fibrositis might with advantage be divided somewhat as follows into three groups.

1 Primary fibrositis, the type which is being discussed in this paper

2 Symptomatic fibrositis, by which is meant fibrositis which merely indicates the presence of some more deep-seated lesion. Examples of this are encountered in cases of spondylitis ankylopoietica, rheumatoid (atrophic) arthritis, diabetes, and often trauma.

3 Senile fibrositis, which may be classified separately, since therapeutically I have found that the prognosis is very poor.

The modern tendency with injection treatment is toward measures aimed at desensitization rather than toward specific immunization, as was the fashion a few years ago. Success may therefore be found at both ends of the therapeutic scale, either by massive doses of protein or T. A. B., or else by minute doses of polyvalent vaccines, as advocated by Crowe. The former method however is apt to produce unpleasant results in frail patients which may overshadow its value for the fibrositis, while the latter method, owing to the considerable period over which it has to be administered, is always liable to the criticism that the disease might in this interval have alleviated itself by natural means anyhow.

When the pain can be localized to one or two definite spots or nodules, the injection of a small quantity of a local anesthetic, or even simple needling, will often result in relief.

It is pointed out by most writers on the subject of fibrositis that any method of treatment which will produce copious sweating is likely to produce improvement in this disease. This is explained by them as being due to a restoration of the normal functioning of the skin. I have often wondered however whether the benefit produced is not due more directly to the elimination of sodium chloride by this route. A salt free diet is of considerable benefit in this condition, more, however, perhaps from a prophylactic point of view than as a curative measure once an attack has started. These patients should in addition increase their fluid intake to a minimum of five pints a day. In cases believed to have a metabolic basis, sensitivity to particular foodstuffs must be carefully inquired into. In Germany the skin protein tests are sometimes performed for this purpose, as in cases of asthma or hay fever. Alcohol is generally prohibited in fibrositis but when this is harmful the patient is, in my experience, generally aware of the fact and has, if intelligent, already "gone dry."

In acute cases, as in gout, it is important that the bowels shall act briskly. Calomel followed by salts, which may well be taken each morning until the patient is cured, is probably best. Colonic lavage will be found in certain cases to be of great value in the later stages but should never be permitted too frequently.

Medicinally the chief indication is for drugs of the analgesic groups. These may be of the types which act locally at the site of the pain, such as acetylsalicylic acid and the salicylates, or those which act centrally through the higher centers such as aminopyrine or the barbiturates. The thiosinamine group are also of value by injection and act by producing a state rather similar to mild protein shock. Of the value of histamine given by injection it is too early to speak with certainty, but it seems as though this substance is of definite value when the lesion is in the muscle substance rather than in an area chiefly composed of avascular fibrous tissue. On general principles the alkalis seem to be of value in fibrositis. The salts of gold which we have in England have been using fairly extensively in the rheumatic group are useless in fibrositis and may be harmful. The use

of iodine in some form is traditional, although its employment is empirical.

Of physical methods heat and massage are the two chief indications. Heat should be prolonged and penetrating. Infra-red rays are probably better than radiant heat and in certain cases, as when the muscles of the back are affected, diathermy is best of all. If the effects of dry heat of this sort are disappointing, it is generally worth trying the effect of moist heat in the form of hot soda baths, mud packs or mustard poultices, while the contrast douche (alternate hot and cold water from jets) when it is available is both stimulating and analgesic. Heat should be given without massage during the stage of effusion, and massage added when this acute phase is over. Rubefacient ointments should be rubbed in by the patient at home, while in some cases actual blistering as counterirritation will give results with local pains.

Massage when used in the treatment of fibrositis must be deep and will therefore be painful. It is essential however that the fibrous nodules should be thoroughly broken up, as they can be, by the trained fingers of the masseur. If the patient is unable to relax his muscles sufficiently for this purpose on account of the pain, an analgesic should be administered previous to this treatment and the period of preliminary heat prolonged. When in spite of these measures the muscles tend to go into spasm, histamine ionization may be given for a few applications. Massage must however be resumed later, even if the pain has been banished, since unless the nodules are destroyed relapse is ultimately almost certain.

After an acute attack of fibrositis the muscles, if carefully examined, will frequently be found to be somewhat wasted, presumably from disuse, and if this is neglected a condition of mild fibrosis will become established and the affected area will become permanently a "weak spot." Active postural exercises or sports should therefore be advocated during the period of convalescence or, when the patient is elderly or sedentary, a course of faradic stimulation of the affected muscle groups.

An attack of fibrositis must not be considered by the physician as being of little importance once the pain is gone. Apart from the undesirability of allowing the patient to drift needlessly into a chronic or semi-chronic condition his general resistance is considerably lowered, fibrositis takes it out of a patient quite unduly, and a proper period of convalescence, with possibly a course of tonic spa treatment, will in all cases prove a profitable investment and should be advised.

15 Harley Street, W 1

A Literary Achievement—The Life of Sir William Osler, by Harvey Cushing, to my mind is one of the most extraordinary literary achievements of our day. That a book in two volumes and more than thirteen hundred pages can, in this age, hold the attention of the reader from start to finish is one marvel. That a biographer who knew his subject as intimately as Cushing did Osler, who stood in the affectionate relationship that he did to him, can keep himself entirely out of the picture, is another. And that, in a book that is of necessity crammed with medical detail, there can be drawn the likeness of such a radiant personality, the record of such gracious living is the third. The Life is dedicated to medical students, with the hope that something of Osler's spirit may be conveyed to those of a generation that did not know him, and no one, I think, can read it without feeling how beautifully Cushing has wrought his labor of love and how adequately he has fulfilled his desire.—Miller, C. J. *Some Literary Doctors of Medicine*, *Am J Obst & Gynec* 18:303 (Sept.) 1929

Clinical Notes, Suggestions and New Instruments

SEVERE XEROSTOMIA FROM X-RAY TREATMENT FOR HYPERTRICHOSIS

SIGMUND S. GREENBAUM, M.D. AND HENRY TUMEN, M.D.
PHILADELPHIA

Because of the fairly common attendant dangers, which are both difficult to foresee and difficult to prevent, dermatologists as well as roentgenologists are quite generally opposed to the uncontrolled and widespread use of x-rays or radium in the therapy of hypertrichosis or excessive hair growth. It often happens, however, that where the physician fears to tread the commercially minded layman, who learns of a medical advance and ignores its dangers, doesn't hesitate.

In various parts of the United States a number of patients with untoward cutaneous complications from the use of the commercialized Trichio (x-ray) System in the treatment of hypertrichosis of the face have been observed. These have served to emphasize the danger of using any x-ray "system" in the treatment of this condition. There has been in use in Philadelphia within the past year or two a new x-ray "system" said to employ specially filtered x-rays and which, in the individual whose case history is to follow, was not accompanied by the superficial complications such as cutaneous atrophy and telangiectases so commonly seen. It was, however, followed by deep effects on the salivary glands of the oral mucous membrane and, naturally, their secretions. Radiologists are well aware of and often see such disturbances following high voltage roentgen therapy for malignant growths within the oral cavity. The advertising matter of this concern (Cosmique Laboratories) makes no mention of the possible dangers of the procedure.

Since these patients may first consult their dentist, it appears of general interest to report this rather unusually marked result of high voltage roentgen therapy for a skin condition with unexpected harmful effects on the secreting epithelium of the oral glands.

REPORT OF CASE

A white woman, aged 52, had been previously studied by one of us in the early part of 1934. She had had pulmonary tuberculosis, which had become inactive following sanatorium treatment. Achylia gastrica had been originally discovered a number of years before and was shown to be still present at the time of the original studies by us. At that time, however, there were no oral symptoms. The blood count was quite normal and nothing else of importance was discovered. When seen again in January 1935 she complained of general oral soreness, especially of the tongue, associated with excessive dryness of the mouth, which had developed during the last week of September 1934 and had progressively become worse. The soreness was aggravated by the use of spicy and hot foods and by smoking. The patient stated that her lips felt puckered and that talking markedly aggravated the dryness, as did keeping the mouth open for a short time. The mouth on examination appeared to be dry and lacking salivary secretion. The mucosa itself was definitely drier than normal. The lingual epithelium had an atrophic appearance. The oral examination itself was annoying to the patient, first because the parts touched by the tongue depressor were sensitive and secondly because she was compelled to open and close her mouth repeatedly in an attempt to increase the oral secretions and thus moisten the mucous membranes, which rapidly dried out.

The causes for xerostomia were reviewed and the patient was questioned as to possible exposure to x-rays. This elicited the information that beginning in June 1934 she had received at the hands of a "cosmetologist" about twenty-four x-ray treatments to both sides of her face for excessive hair growth. The last treatment had been given in December 1934, one being given in each week of September, October and November despite the development of progressive oral dryness.

On our advice the x-ray treatments were discontinued during the next year. There was a slight but progressive improvement during the next year and when the patient was last seen, in January 1936, the symptoms had diminished a great deal but were still present to a moderate degree.

ANAPHYLAXIS DUE TO SODIUM MORRHUATE

KENNETH M. LEWIS, M.D., NEW YORK
Assistant Visiting Surgeon, Bellevue Hospital

The injection treatment of varicose veins of the lower extremities has grown in popularity so rapidly during the past five years, and the solutions in use have become so standardized, that attention should be called to a possible danger in the use of sodium morrhuate solutions. Mention has been made in the literature to localized manifestations of allergic reactions to sodium morrhuate, these mainly consisting of urticarial rashes appearing at the site of injection. Of these I have seen a goodly number. Little comment, however, is made about any constitutional reactions. Having had a severe anaphylaxis occur in one of my cases, and noting a similar experience in three other instances among my colleagues, I feel that a real danger exists and that the condition possibly has occurred with greater frequency than might be considered likely. All these cases of anaphylaxis occurred in individuals who had received injections of sodium morrhuate at a preceding interval of a year or more. It would thus seem as though there were some protein liver radical in the sodium morrhuate solutions to which certain individuals become sensitized and in whom later injections with the same solution caused foreign protein allergic reactions. Most of such reactions fortunately consist of local urticarias, but the experience of seeing a severe constitutional anaphylaxis makes one wonder whether the repeated use of this solution in the same patient is altogether safe. The following case is therefore reported.

REPORT OF CASE

Mrs. N. D., aged 35, seen Dec. 14, 1935, gave a history of having had extensive varicosities of both thighs and both legs for a number of years, all of which had been successfully thrombosed by the injection treatment in 1932. The solutions used at this time were 5 per cent sodium morrhuate and quinine and urethane, with a few injections of 20 per cent sodium chloride. There were no reactions at this time, either local or general. In 1934 the patient went through a normal pregnancy, following which a moderate number of varicose veins in the legs and thighs recurred. When I first saw her in December 1935, examination revealed the internal saphenous group of veins in each thigh varicosed and she was advised to have them reinjected. At the first visit only one injection was given, consisting of 1 cc. of 5 per cent sodium morrhuate. No reaction was noted. The patient was seen one week later, at which time she mentioned that she had some itching at the site of the injection during the preceding week but otherwise felt well. At the second visit, 15 cc. of 5 per cent sodium morrhuate was injected in a varicosity in one thigh and 2 cc. of the same solution in the opposite thigh, a total of 35 cc. The injections had just been completed when the patient suddenly complained of feeling ill and very warm. She rapidly went into collapse. The pulse rose to 150 and within a few moments was imperceptible. There was marked dyspnea, pallor of the face and cyanosis of the fingers. The respirations became rapid and shallow. A generalized urticarial rash was then noted and this was quickly followed by spasmodic, severe cramplike pains in the lower part of the abdomen, which could best be compared to labor pains. These were accompanied by severe retching. The blood pressure dropped to 70 systolic, 0 diastolic. The heart sounds were rapid and weak but of fair quality.

Epinephrine 1 1,000 in 10 min. (0.6 cc.) doses were given subcutaneously every ten minutes until a total of 3 cc. had been given and 1 grain (0.065 Gm.) of morphine sulfate in one-third grain (0.02 Gm.) doses every fifteen minutes was given hypodermically. The pulse remained imperceptible for about one hour and then gradually returned to normal over a period of two hours. The whole attack lasted about three hours. The severity of the symptoms remaining about the same for the first hour and slowly subsiding during the remaining time. The patient was allowed to return home five hours after the onset of the attack, but nausea, weakness and recurrent waves of urticaria were present for the ensuing week.

The dramatic suddenness with which this attack occurred, its severity and the real danger of possible death were most impressive particularly as it occurred during a form of therapy which is so generally believed to be unaccompanied by danger.

Inquiry has revealed three similar experiences in different patients, fortunately none of them having a fatal outcome.

It would thus seem as though sodium morrhuate solutions should be used with the greatest care in patients who have previously received the same solution, if a sufficient time has elapsed to allow the development of a foreign protein sensitivity. One should be doubly careful with individuals who are subject to asthma, hay fever or any other allergic phenomena.

59 East Fifty-Fourth Street

Special Article

THE PHARMACOPEIA AND THE PHYSICIAN

THE USE OF CATHARTICS

OSCAR W. BETHEA, M.D.

Professor of Clinical Medicine, Tulane University of Louisiana
School of Medicine
NEW ORLEANS

This is one of a series of articles written by eminent clinicians for the purpose of extending information concerning the official medicines. The twenty-four articles in this series have been planned and developed through the cooperation of the U. S. Pharmacopeial Committee of Revision and The Journal of the American Medical Association.—Ed

Over a long period in the history of medicine there was an enthusiasm for depletion which is difficult for physicians at present to understand. This included bleeding by venesection, scarification and cupping, leeching, emesis, diaphoresis, diuresis and purging. These were employed with what seems to us today "a gay and reckless abandon." The present tendency is to confine the use of such measures to cases presenting definite indications and our conception of these is rapidly becoming more critical. More or less indiscriminate purgation is the last of the aforementioned measures to be materially restricted. In a recent survey of two of the largest hospitals in New Orleans, I¹ found that of all patients admitted to the medical services about 33 per cent received a large dose of some cathartic within the first twenty-four hours, 11 per cent were so favored in the second twenty-four hours. There is some evidence of a decreasing tendency to prescribe cathartics.²

The persistent tendency by the public to the use of purgatives is largely the result of the influence of commercial advertising. The exploitation of the public in this particular is a disgrace to our modern civilization. In this campaign the welfare of suffering humanity is given secondary consideration, if any at all.

Before deciding to administer an active cathartic to a patient, one should certainly carefully weigh the indications and contraindications. When one considers the limited possible value of emptying the intestinal tract of its normal contents and the probable disadvantages such as dehydration, exhaustion, discomfort, loss of nutrition, disturbance of sleep and even possible danger one should at least consider all available data. Some of the possible disadvantages are well illustrated in the recent statistics³ from the Charity Hospital at New

1. Bethea, O. W. The Use and Abuse of Purgatives. *In* *Ann. N. Y. Acad. Sci.* 24: 239 (March) 1934.

2. Gathercoal, W. N. The Prescription Ingredient Survey. *Am. J. Pharm.* 1933.

3. Maes, Urban. Personal communication to the author.

Orleans covering acute appendicitis. It was shown that, of those patients receiving no purgative before operation, one in every ninety-six died, of those who had taken a purgative before operation, one in every eleven died, of those who had been the victim of repeated purgation, one in every four died.

Cathartics have been divided into various groups, such as laxatives, hydrogogues and drastics. One of the most convenient groupings for study is the following ⁴

- 1 Drugs, such as liquid petrolatum, that act only mechanically by reason of their bulk or consistency
- 2 Drugs, such as agar, that act by absorbing and holding water, and thereby preventing its absorption from the bowel
- 3 Saline cathartics, such as magnesium sulfate, that act partly by preventing absorption of water and partly by a direct action on the bowel wall
- 4 Drugs, such as cascara sagrada, containing a quinone group. These act mainly on the colon
- 5 Drugs, such as podophyllum, containing a resinous body, which is slowly broken down, releasing an irritant principle
- 6 Drugs, such as castor oil, containing unsaturated fats
- 7 Inorganic drugs, such as mercury and sulfur

I shall divide these agents into two general groups based on their therapeutic use

- 1 Those employed for an acute condition, that is, to meet the present need of the patient
- 2 Those employed for longer periods (as in chronic constipation or edema)

I am not considering here such measures for emptying the alimentary tract as enemas and suppositories.

In selecting a purgative agent for the immediate need of the patient, it is desirable to choose one that will produce the desired result with the least possible discomfort or danger and will have the minimum of undesirable side effects (such as continued purgation). It should also be an agent that may be taken with convenience and retained with certainty. The drugs in this group are so often in the family medicine cabinet that it is seldom necessary to write a prescription. In most instances it is also best to inquire into the history of the patient as to his experience in the past. A drug that may be very palatable to one may be exceedingly objectionable to another. Again, a dose of a certain amount may be satisfactory to one individual and not to another. In other words, when it comes to purgation every patient is a law unto himself.

Magnesium Sulfate, U S P, is probably the most widely used purgative. It is efficient in action, rarely causes discomfort, has few undesirable side-effects, and the principal disadvantage is an unpleasant taste, which may be eliminated to a large extent by dissolving the salt in some palatable fruit juice. Its mode of action is characteristically that of the salines. I seldom find it necessary to give more than one-half ounce (15 Gm) at a dose. Why the standard ward dosage in many institutions should be 1 or 1½ ounces (30 to 45 Gm) I have never been able to understand.

Solution of Magnesium Citrate, U S P, a flavored, carbonated saline, is often recommended by physicians. It is seldom that a prescription is written for it, as it is so well known to every one. It is much more expensive per dose than most of the other purgative agents and this has probably militated against its general use. It is exceedingly nauseating to many persons and not infrequently causes violent and continued purgation.

Magnesia Magma, U S P, commonly known as milk of magnesia, is palatable to most persons and is

especially easy to administer to most children. Its alkalinity makes it particularly desirable in hyperacidity, and it neutralizes hydrochloric acid in the stomach without the liberation of carbon dioxide. It may be administered plain or stirred in cold water. Its continued use may cause discomfort in the rectal region, characterized particularly by a sensation of burning.

Sedlitz Powders, U S P, also known as compound effervescent powders, form one of the most palatable mild laxatives available. The taste is not objectionable to most persons and, when added to water for administering, it forms an alkaline, effervescent, carbonated beverage that rarely causes nausea and is usually satisfactory in results.

The sodium phosphates comprise several preparations, all of which are inexpensive and fairly satisfactory in their effect.

Sodium Phosphate, U S P, is not often prescribed as such. It is extensively used in some of the proprietary preparations, which are usually concentrated solutions made by adding citric acid. Effervescent Sodium Phosphate (U S P) is a granular powder which, when added to water, forms a fairly pleasant carbonated drink. It is put up in 2 to 4 ounce bottles and is employed particularly as an early morning laxative in chronic constipation.

Sodium Biphosphate, U S P, frequently called sodium acid phosphate, is an excellent laxative and is frequently used to acidify the urine. For the latter purpose its usefulness is somewhat limited by its laxative quality.

Magnesium Oxide, U S P, is seldom employed as a purgative agent but is extensively prescribed to neutralize gastric acidity. Hence its laxative quality must be given consideration.

Magnesium Carbonate, U S P, is not often prescribed as such. I remember that in my earlier years this agent pressed into blocks was a very common domestic article. It was used as a face powder by the ladies of the household, as a dusting powder for the children, and small amounts were nibbled off the block for acid stomach while larger bites were taken when its laxative effect was desired. An agent with so wide a field of usefulness hardly deserved to fall into disuse.

Castor Oil, U S P, would probably come next to magnesium sulfate in popular usage, at least if bulk is considered. The old, crude oil that we remember from our earlier years often had a disagreeable odor and always a disgusting taste. The highly refined oil that may now be purchased is odorless and practically tasteless. The principal disadvantage in its use is the psychic inhibition that we have carried over from the days of outraged youth. When we remember the limitations of the sense of taste, we realize that most of the unpleasantness of this drug, against which childhood has rebelled throughout the generations, is really due to smell, and the old practice of holding the nose when taking the dose was not without value. Many plans have been suggested for making castor oil less disagreeable. The so-called tasteless preparations that are made by sweetening the oil with saccharin and flavoring it with some volatile oil are sometimes more atrocious than the oil itself, even in its crudest state, could ever hope to be. It may be administered in lemon juice, pineapple juice, ginger ale or in various other ways. Some prefer to take it warm. One of the most palatable ways of administering castor oil, and one that is particularly effective when there is acute indigestion or nausea from any cause, is to put the dose of oil

⁴ Solis Cohen, Solomon and Githens T S Pharmacotherapeutics
Materia Medica Drug Action New York, D Appleton & Co 1928

into a glass, add 4 cc (1 fluidrachm) of paregoric (Camphorated Tincture of Opium U S P), heat it up vigorously with a spoon, and let the patient gulp it at one swallow. This process divides the oil into small globules, each of which is surrounded by a coating of the paregoric. Should the first dose be vomited, it should be repeated immediately, the second dose is practically always retained. Castor oil has the quality of purging and then lessening intestinal activity. Occasionally some medical men speak of this agent being toxic. "It may be given in large quantities without any symptoms except its mild, laxative action."⁵ It is principally absorbed from the small intestine, so its action on the colon is indirect.

Calomel (Mild Mercurous Chloride, U S P) one time was the "magnum donum Dei" of the medical profession. It was the beginning and sometimes the end of most therapeutic effort. Today it is rapidly falling into disuse. To a large extent the same may be said of Mass of Mercury, U S P, and Mercury with Chalk, U S P. These agents are still employed to a considerable extent in the treatment of syphilis in children.

Phenolphthalein, U S P, is increasing in favor with the profession, even as a prescription ingredient. It is extensively employed in many proprietary remedies. It is largely without toxic action and, though skin eruptions sometimes occur, it is a fairly safe and reliable laxative and is so easily administered, even to children, that its place in therapy has been easily established.

Naturally many agents that will be considered in the next section under those for continued use may be given for temporary need if a sufficiently large dose is employed.

The use of cathartic drugs is often indicated for extended periods of time, but particularly in the treatment of chronic constipation the value of proper diet, sufficient water, exercise, and the establishment of the habit of intestinal elimination through patient effort must be remembered. Bastedo⁶ has quaintly remarked that "the prescribing of purgatives is oftentimes an indication of laziness on the part of the physician."

"With the majority of patients, constipation is due to functional rather than mechanical causes, and these principally affect the large bowel."⁷ "Eighty-five per cent of constipation is functional and nearly all of these are due to faulty habit."⁸

In the presence of edema, the use of hydragogue purgatives is guided entirely by the evident requirements of the particular patient. In chronic constipation the object should be to give cathartics only until the condition can be corrected and a proper habit established. In any event a preparation should be selected that is palatable if possible, that will cause a minimum of interference with digestion, that will be free from discomfort, that will not increase the purgative habit, and that will be free from other unfavorable side effects, such as a tendency to cause hemorrhoids.

Olive Oil U S P, is palatable to many persons and not particularly objectionable to the majority. It is nutritious, tends to lessen gastric acidity, favors emptying of the gallbladder, and directly or indirectly stimulates the pancreatic output. As a laxative it is usually

best taken in one dose at bedtime, though some find it more satisfactory to take divided amounts two or three times during the day. It occasionally causes abdominal discomfort, though such reaction is the exception. As much as I regret to have such a statement emanate from the South, it cannot be replaced satisfactorily by Cottonseed Oil, U S P, as in the process of refining this latter product certain fatty acids are removed on which olive oil depends for part of its effect. I recently visited a ward containing eighteen patients suffering from pulmonary tuberculosis for whom olive oil had been the only laxative employed for many months.

Liquid Petrolatum, U S P, has continued to hold a prominent place in the treatment of chronic constipation and some kindred disorders. It is not absorbed, passing through the intestine unchanged. "Its action is that of a mechanical lubricant"⁹ and, though it does have some tendency to increase the bulk of the intestinal content, it does not appreciably increase peristalsis but makes more effective the peristalsis that is already operative. It is particularly valuable in such conditions as hemorrhoids, anal fissure and those conditions in which some part of the lumen of the intestinal tract is reduced in caliber.

The Emulsion of Liquid Petrolatum, U S P, has been extensively advertised by the various pharmaceutical houses, and many proprietary products are on the market. Some of these claim to have particular value because of the fact that the emulsion is made with agar. This is misleading because the amount of agar present is insufficient to have any therapeutic effect, and there is enough water present in the emulsion to negate any possible benefit from the agar. It would certainly seem probable that all liquid petrolatum preparations would interfere with digestion and assimilation to a certain extent.

Cascara Sagrada, U S P, as now put on the market is not only effective but almost free from discomfort. While the extract (U S P) is sometimes employed the drug is principally ordered, as the fluidextract (U S P) or the aromatic fluidextract (U S P). These are prescribed alone or with milk of magnesia as previously mentioned, or small amounts are added to various formulas to make them laxative. It should be remembered that only the aromatic fluidextract is miscible with aqueous solutions. In ordering pills or tablets or in instructing patients to purchase and use them, physicians should be careful to avoid the various pharmaceutical combinations that contain drastic cathartics.

Sodium Sulfate, U S P, is again coming into popularity. Faust prefers it to all other agents as a purgative to be used after an anthelmintic. One of the most pleasant plans of administering it for continued use is to prescribe it with an equal amount of Potassium Bitartrate, U S P, and have the patient take one or two teaspoonfuls of this mixture with fruit juice on first awakening in the morning.

Agar, U S P, is seldom a prescription ingredient but often is employed to give bulk to the intestinal content.

Senna, U S P, is a popular domestic remedy. It is sometimes employed by chewing the leaves but more frequently by making them into a tea. The excellent quality of this agent is largely overlooked by the medical profession. Compound Powder of Senna, U S P is sometimes prescribed.

⁹ Sollmann Torald, A Manual of Pharmacology Philadelphia W. F. Saunders Company 1932.

Rhubarb and its preparations (U S P) and sulfur in its various forms (U S P) are still used, though with decreasing frequency

The old "drastics" familiar to the past generations of medicos have largely and deservedly fallen into disuse. They are not necessary in modern medicine and their use was certainly fraught with an element of danger. The least objectionable of these, Aloin, U S P, and Podophyllin, U S P, are still prescribed for certain definite indications

SUMMARY

Cathartics should not be used without definite indications

In the selection of a purgative agent, due attention should be given to the indications and contraindications presented by the particular patient

The United States Pharmacopeia XI contains a variety of properly standardized cathartic drugs that will meet the therapeutic requirements in most if not all instances

Council on Physical Therapy

THE COUNCIL ON PHYSICAL THERAPY HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT
HOWARD A. CARTER Secretary

FISCHER MODEL "SWI-12" SHORT WAVE APPARATUS ACCEPTABLE

Manufacturer H G Fischer & Company, Chicago

This device is recommended for medical and surgical diathermy. High frequency radiations may be applied by cuff electrodes, electromagnetic coils and pad electrodes for medical diathermy applications, and terminals are provided for surgical electrodes. The wavelength of this unit is 12 meters. Electrodes or applicators furnished with the apparatus consist of pads, cuffs, and insulated cables. The circuit is the well known push-pull type, having two oscillator and two rectifier tubes. The patient's circuit is inductively coupled to the tank circuit. The variable condenser is used to tune the patient's circuit to electrical resonance. When this machine is operated

under full load, it draws not more than 700 watts. Since no reliable method has been proposed to measure the output of energy available to the patient, the value is not given. (Figure 2 is the diagram of the circuit)

The manufacturer submitted evidence substantiating the heating ability of the unit. For the electric field method cuff electrodes were applied to the thigh, one posterior to the hip and one anterior to the knee. The cuff electrodes used in the investigation were made of metal, surrounded by thick protecting rubber. Several layers of toweling

Fig 1 — Fischer SWI 12 short wave machine.

or felt, or both materials, were placed next to the skin to absorb perspiration and also to permit suitable spacing of electrodes. In the case of the electromagnetic field method a heavy, insulated coil was wrapped around the thigh and separated from the skin by one half inch of toweling and felt.

The human subjects were all vigorous, adult male medical students, ranging in weight from 150 to 180 pounds (68 to 81.6 Kg). Two trocars placed in hard rubber cannulas were inserted into the thigh. One was introduced at right angles to the thigh and straight down into the depth of the muscle tissue until the instrument was at an approximate depth of 2 inches or until the femur was encountered. The second was introduced as nearly parallel to the skin as possible and subcutaneously at an approximate depth of one eighth inch. The

trocars were removed, leaving the rubber cannula in situ. Temperature measurements were taken by means of thermocouples of the hypodermic needle type and introduced through the cannulas. The third thermocouple, placed on the skin surface underneath the cuffs, was used to measure skin surface temperature. Cold junctions were immersed in ice enclosed in a quart vacuum bottle. The readings were observed on a Leeds & Northrop portable potentiometer. The thermocouples were calibrated in degrees Fahrenheit against a Bureau of Standards thermometer. Initial temperatures were taken and then each subject was submitted to a twenty-minute application of short wave diathermy energy of maximum current strength at his tolerance. At the end of this period the temperatures

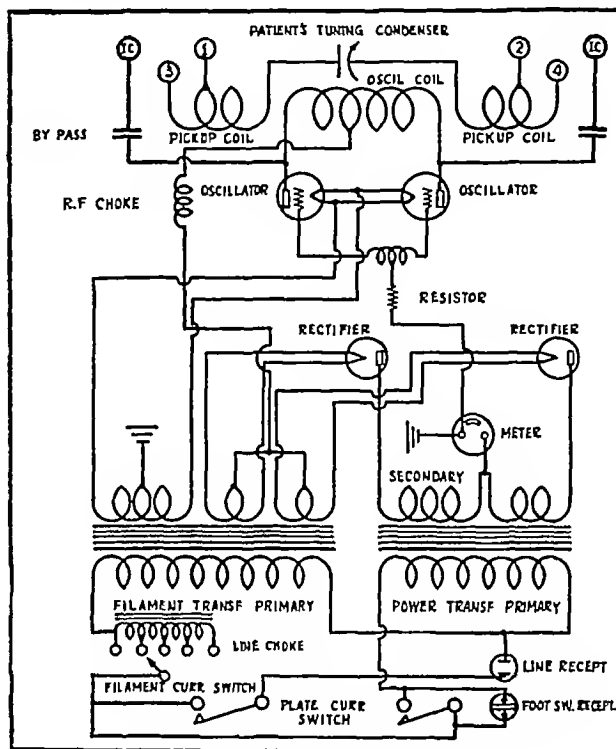

Fig 2 — Schematic diagram of circuit

were again recorded. Temperatures were observed at intervals of one minute until the temperature began to drop. The highest temperature attained was recorded as the final temperature in each instance. Then the thigh was permitted to cool until the temperature dropped to or near the initial temperature and the observation was repeated. Each reading in the table is the average of six observations

Temperature Readings

Technique	Wave-length	Muscle Temperature		Subcutaneous Temperature		Skin Surface Temperature		Oral Temperature	
		Initial	Final	Initial	Final	Initial	Final	Initial	Final
Cuff	12	99.50	106.22	96.64	103.76	96.62	98.72	98.4	99.26
Coil	12	99.73	106.60	97.33	105.83	94.55	99.37	98.67	99.60

Data on the temperature rise when pad or air gap electrodes were employed were not submitted. The temperature rise of the transformer, after the machine had been operated at full load for two hours, came within the limits of safety prescribed by the Council. The shipping weight of the apparatus is about 155 pounds. Burns may be produced but may be avoided by ordinary precaution. Their likelihood to occur is much less than with conventional diathermy.

The machine was installed in a clinic acceptable to the Council and operated under actual clinical conditions. It was

reported as giving satisfactory service. In view of the favorable report based on the performance of this unit when cuff electrodes or coil technic was used, the Council on Physical Therapy voted to include the Fischer Model "SWI-12" Short Wave Apparatus in its list of accepted devices.

Council on Pharmacy and Chemistry

PRELIMINARY REPORT OF THE COUNCIL

THE COUNCIL HAS AUTHORIZED PUBLICATION OF THE FOLLOWING
PRELIMINARY REPORT
PAUL NICHOLAS LEECH, Secretary

THE USE OF TRICHLOROETHYLENE FOR GENERAL ANESTHESIA

The chemical trichloroethylene was first described in 1864. In 1915 Plessner¹ found symptoms of poisoning in those working with the preparation commercially and noted the special affinity of this agent for the sensory fibers of the trigeminal nerve. Oppenheim² suggested its use by inhalation in the treatment of trigeminal neuralgia, and for that purpose it is accepted for inclusion in New and Nonofficial Remedies. Recently, however, trichloroethylene has been used as a general anesthetic. The product used for this purpose differed from that used in the treatment of trigeminal neuralgia. It contained no added diluent or stabilizing agent and the boiling points were more closely defined.

The evidence for the usefulness of this agent in general anesthesia consists of one experimental³ and one clinical report,⁴ both by the same group of workers. Jackson and his associates claim these advantages for trichloroethylene (for anesthesia): it is safe where there is any fire hazard (cautery), because it is noninflammable and nonexplosive, the fumes do not spread, and it is more pleasant than ether. It acts like ethylene (and in stronger concentrations, like ether) in animals. Jackson³ devised a special apparatus for its administration and used it experimentally and clinically. It is claimed that the machine produces the vapors of trichloroethylene continuously in any strength desired.

The clinical report⁴ of 300 anesthetics and analgesias included twenty-five dental cases, twenty-five cases of removal of venereal warts and 198 cervical cauterizations. The authors state:

As yet we have not used trichloroethylene in laparotomies or other major surgical procedures (except in experimental animals).

Trichloroethylene is administered by starting with a very dilute vapor (mixture) of trichloroethylene in air and slowly increasing the concentration until the gage on a special (proprietary) apparatus records half trichloroethylene and half air (there does not seem to be information available on the actual concentration which produces satisfactory anesthesia). It is stated not to be volatile and that "a small amount goes a long way."³ Its chief danger lies in its rapid effect. This applies especially to the first stage. In one case this rapidity resulted in a respiratory failure (recovery by artificial respiration), which was attributed to a "slight overdose."³

According to reports⁴ there is flushing of the face, mild lacrimation, and slight increase in the pulse rate in the first stage. In the second stage there is mild excitement, twitching of the hands and face, lateral and rotary nystagmus and an increase in pulse rate of from 10 to 20. Severe excitement was attributed to improper administration. Eight of the 300 patients became so mildly excited that the third stage could not be induced. Three of these patients are said to have been alcoholic.

Neurol., Feb. 14, 1916. Monatsschr. f. Psychiat. u. Neurol. 44:374, 1918, quoted by Ojemick. Ignaz. Trichloroethylene Treatment of Trigeminal Neuralgia, J. A. M. A. 91:1085 (Oct. 13), 1928.

2 Oppenheim. Neurol. Zentralbl. 34:918, 1915, quoted by Ojemick.

3 Jackson, D. E. A Study of Analgesia and Anesthesia, with Special Reference to Such Subjects as Trichloroethylene and Vinethene Together with Apparatus for Their Administration. Anesth. & Analg. 13:198 (Sept. Oct.) 1934.

4 Stricker. Cecil. Goldblatt. Samuel. Warm. I. S. and Jackson. D. E. Clinical Experiences with the Use of Trichloroethylene on the Production of Over 300 Analgesias and Anesthetics. Anesth. & Analg. 14:68 (March-April) 1935.

addicts and the other five very emotional girls.⁴ Complete relaxation occurs in the third stage. The pulse is full and strong and respirations are more rapid and shallower. It is stated that there may be slight [?] cyanosis. In clinical cases recovery generally occurred in about five minutes.⁴

Jackson³ noted that the formula suggested chloroform and considered the possibility of comparable liver effects. Herzberg⁵ compared the observations in three dogs killed with prolonged trichloroethylene anesthetics and two dogs killed by electrocution. He concluded that the changes in the anesthetized dogs were not specifically due to the anesthetic agent because the control (electrocuted) dogs showed similar (principally liver) changes.⁵ This evidence seems inadequate and the conclusion unwarranted. Apparently basing his opinion on this work, Jackson³ notes that, as far as liver effect is concerned, ether resembles chloroform more than trichloroethylene does.

The reports of trigeminal effects of this agent were noted, but it is suggested by the authors that they are in error. Jackson states:

In the light of the work we are here reporting it is fairly apparent that the symptoms produced by the inhalation of trichloroethylene (as facial neuralgia) vapors were varying degrees of general anesthesia and that pathological conditions observed were due either to contamination in the trichloroethylene or more likely to altogether different causes.

This statement seems unwarranted after considering the older literature on the use of this agent. The trigeminal effect has generally been noted to persist after all other effects have passed. It should be determined just what does become of this trigeminal sensory paralysis after such anesthesia. To attribute pathological conditions to contaminations seems especially dangerous in view of the possible phosgene production (by decomposition), which is not mentioned by the authors.

The Council held that the available evidence does not justify the acceptance of trichloroethylene for use as a general anesthetic and postponed consideration to await (a) solution of the question of potential toxicity of decomposition products of the drug and (b) development of the evidence to substantiate the claims for its clinical use as a general anesthetic.

NEW AND NONOFFICIAL REMEDIES

THE FOLLOWING ADDITIONAL ARTICLES HAVE BEEN ACCEPTED AS FORMING TO THE RULES OF THE COUNCIL ON PHARMACY AND CHEMISTRY OF THE AMERICAN MEDICAL ASSOCIATION FOR ADMISSION TO NEW AND NONOFFICIAL REMEDIES. A COPY OF THE RULES ON WHICH THE COUNCIL BASES ITS ACTION WILL BE SENT ON APPLICATION.

PAUL NICHOLAS LEECH, Secretary

CAFFEINE WITH SODIUM BENZOATE—"A mixture of caffeine and sodium benzoate, containing when dried to constant weight at 80 C., not less than 47 per cent and not more than 50 per cent of anhydrous caffeine (C₈H₁₀N₄O₂) and not less than 50 per cent and not more than 43 per cent of sodium benzoate (NaC₇H₅O₂)."
U. S. P.

For standards see the U. S. Pharmacopeia under Caffeine cum Sodium Benzoate.

Ampules Solution Caffeine Sodium Benzoate 2 cc. Each 2 cc. contains 0.48 Gm. (7½ grains) 24.33 per cent solution marketed in packages of ten 2 cc. size ampules.

Prepared by the U. S. Standard Products Co. Woodworth, Wis.

I V C HALIBUT LIVER OIL WITH VITAMIN D CONCENTRATE IN NEUTRAL OIL—Halibut liver oil to which has been added a concentrate of liver oils of Gadus morrhua, Ophiodon elongatus and Anoplopoma fimbria. It is assayed to have a potency of not less than 59,000 units (U. S. P.) of vitamin A per gram and not less than 1,990 units (U. S. P.) of vitamin D per gram.

Manufactured by the International Vitamin Corporation, New York. The vitamin D concentrate used is made under U. S. patent 1,607,791. U. S. trademark 314,818.

Capsules I V C Halibut Liver Oil with Vitamin D Concentrate in Neutral Oil 3 minims.—The content of each capsule is assayed to contain not less than 10,000 units (U. S. P.) of vitamin A and not less than 945 units (U. S. P.) of vitamin D.

5 Herzberg, Mortimer. The Histology of Tissue Taken from Animals Killed by Prolonged Administration of Concentrated Vapor of Trichloroethylene. Anesth. & Analg. 13:203 (Sept. Oct.) 1934.

HALIBUT LIVER OIL (See New and Nonofficial Remedies, 1936, p 459)

The following dosage form has been accepted

Capsules 1 V C Halibut Liver Oil Plain 3 minims—The content of each capsule is assayed to contain not less than 10 000 units (U S P) of vitamin A and not less than 170 units (U S P) of vitamin D
Manufactured by the International Vitamin Corporation New York
No U S patent. U S trademark 314 818

SCARLET FEVER STREPTOCOCCUS TOXIN (See New and Nonofficial Remedies, 1936, p 388)

The National Drug Co, Philadelphia

Scarlet Fever Streptococcus Toxin for Immunization National (See New and Nonofficial Remedies 1936 p 388)—Also marketed in packages of six 10 cc. vials of toxin one containing 500 skin test doses one containing 2 000 skin test doses one containing 8 000 skin test doses one containing 25 000 skin test doses and two containing 80 000 skin test doses

BUTESIN PICRATE (See New and Nonofficial Remedies, 1936, p 71)

The following additional dosage form has been accepted

Butesin Picrate Ointment with Metaphen Butesin picrate 1 per cent and metaphen 1 5 000 incorporated in an ointment base composed of white wax paraffin, petrolatum sodium borate and water 99 per cent

ANTIPNEUMOCOCCUS SERUM TYPES I AND II COMBINED (See New and Nonofficial Remedies, 1936, p 374)

E. R. Squibb & Sons, New York

Concentrated Anti Pneumococci Serum Types I and II (See New and Nonofficial Remedies 1936 p 375) Also marketed in packages of one syringe containing 20 000 units each of types I and II pneumococci

Council on Foods

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING GENERAL DECISIONS.

FRANKLIN C. BING, Secretary

FRESH COMPRESSED YEAST, DRIED YEAST, AND YEAST EXTRACTS ARE SPECIAL PURPOSE FOODS

Compressed fresh yeast, dried yeast and yeast extracts ordinarily are not classed among the usual table foods but are looked on as foods with usefulness restricted to special purposes. These products are useful for increasing the vitamin B₁ and G content of the diet. Fresh yeast and dried yeast if taken in sufficient quantity have a mild laxative effect on many persons. Compressed fresh yeast, dried yeast and yeast extracts therefore come within that class of foods designated as "special purpose foods" in the Rules and Regulations of the Council on Foods.

To be eligible for acceptance, the labels and advertising for these yeast products shall prominently display the designation "special purpose food," list the ingredients other than yeast substances, state the percentages in close proximity to product name, and give the vitamin B₁ and G unitages determined by biologic assay. Special claims for yeast products must have Council approval before use in advertising.

AMENDMENT OF COUNCIL DECISION "VITAMIN E CLAIMS FOR PUBLIC ADVERTISING"

There are at present no adequate scientific data establishing the role of vitamin E in human dietetics. This vitamin is present in many common foods, the necessary amount, so far as is known, being acquired with any ordinary diet. Statements or claims referring to vitamin E in advertising to the public imply a need for special sources of the vitamin that is not warranted by present knowledge. Neither claims for vitamin E nor mention of the vitamin shall appear on food labels or in advertising addressed to the public, nor will such claims be recognized if they appear in advertising addressed to the profession if directly or inferentially such advertising recommends the use of the preparation because of its vitamin E content.

THE COUNCIL ON FOODS HAS AUTHORIZED PUBLICATION OF THE FOLLOWING REPORT

FRANKLIN C. BING, Secretary

KELLOGG'S ALL BRAN OMITTED FROM THE LIST OF ACCEPTED FOODS

Submitted advertising for Kellogg's All Bran (THE JOURNAL, Feb 9, 1935, p 474) has repeatedly been found to be in conflict with the spirit and intent of the General Decisions on Food and Food Advertising of the Council on Foods. While much of the explanatory part of the advertising may be within the bounds of the technical criticisms that the Council has made to the Kellogg Company in the past, the total effect is to impress the reader that Kellogg's All Bran is the answer to substantially all constipation difficulties. The qualification insisted on by the Council ("due to insufficient bulk") is observed, to be sure, but its force is minimized by the general effect of the presentation. Statements such as "So I have been eating it for two or three weeks, and my constipation (due to insufficient bulk) has gone, and I was constipated for 25 years or more" illustrate the type of objectionable advertising copy that has been used. It is not reasonable to suppose that taking a small amount of All Bran for two or three weeks could correct constipation of twenty-five years' duration. Furthermore, such testimonials of a health, medicinal or therapeutic character, or with such implication, are in conflict with the General Decisions of the Council.

The exclamatory parts of the advertising, such as the frequent short phrases and display heads, are too often of the "patent medicine" order.

Disparaging statements such as "For 34 years, I had to take pills, salts, oils, teas, or other fluids, which did more harm than good" and "Finds All-Bran better than Pills, Salts and Oils" abound in the copy.

The reference to symptoms that may accompany constipation, together with the implication that Kellogg's All-Bran will correct these conditions, is contrary to the Rules of the Council.

It is the contention of the Council that advertising for accepted food products should not be predicated on personal charm and social preferment, as illustrated in statements such as "So many women lose their good looks after thirty. They fail to realize the importance of what they eat day after day" with the implication that bran will cure the discomfort, headaches, poor appetite and listlessness of the person who has lost her good looks.

The Council voted, in view of the continued objectionable advertising for products of the Kellogg Company and the claims made, that acceptance of all products of the Kellogg Company be rescinded, and that the products will be reconsidered without prejudice if presented not earlier than one year from date of notification, to determine whether or not the policy of the firm has changed sufficiently to warrant reacceptance of the products at that time.

When the foregoing report was transmitted to the Kellogg Company and to its advertising agency for All-Bran, N W Ayer & Son, Inc., the latter replied in part:

"You know we regret not being able to see eye to eye with you on this advertising, particularly with reference to testimonials."

"However, in the published statement, you have expressed the rules of your Association and have been entirely fair in pointing out where our advertising did not observe those rules."

We are sorry for this disagreement in views. But at least we wish to thank you for the great amount of time and thought you have given to this whole situation."

The Council has recently summarized (THE JOURNAL, Sept. 12 1936, p 874) the available evidence regarding the significance of bran in the diet. Bran is a product which is capable of contributing to the nutritive requirements in a number of respects notably as a source of roughage. There are individuals, however, who cannot tolerate bran. The Council believes advertising which artfully conceals the potential danger of the indiscriminate use of bran is contrary to the best interests of the public.

The Council therefore has reaffirmed its stand and has authorized publication of this report.

ACCIDENTAL BURNS IN CHILDREN

Accidents among children, according to a report just published by the United States Public Health Service,¹ constitute a significant menace to infant lives. Moreover, accidental burns (conflagration excepted), are the leading cause of death at ages 1, 2 and 3 years, and for the age group under 5 years as a whole. This is due, in part, to the relatively low death rates from other causes after the first year and up to the fifth, which allow the deaths from burns to assume such a leading place. Another fact looms with increasing importance—accidental deaths as a whole bid fair to nullify many of the gains that have been made through preventive medicine. What a strange paradox, unflattering to our civilization—we can save children from diphtheria, only to have them burned to death.

The study by the public health authorities covered the years from 1925 through 1932. Causes of death included are, according to the International List of Causes of Death, "burns (conflagration excepted, of any organ or part), by boiling liquid, boiling water, coal oil, corrosive substance, fall with lighted lamp, fire, gasoline, kerosene, molten metal, petroleum, steam, sulfuric acid and vitriol, dermatitis actinica and ambustionis, effects of corrosives, radium and x-rays, explosion of gasoline, kerosene and lamp, fall into fire, fire (conflagration excepted), lamp accident, playing with fire, scald of any part of the body by steam, and sunburn." The study is divided into four regional groups, covering the forty registration states of 1925 and the District of Columbia: Northeastern,² North Central,³ Southeastern⁴ and Western.⁵ The data collected for these four regions show that the actual number of

deaths from burns in each of the groups decreased from 1925 to 1932, but the percentage distribution of the deaths by age varied little. In each geographical division, the lowest limit of relative mortality due to burns (ratio of fatalities from accidental burns to fatalities from all accidents) was about the same—3 per cent, and occurred in the age group 10 to 14. The upper limits of relative mortality are as follows: South eastern, 57 per cent, Northeastern, 43 per cent, North Central, 38 per cent, Western, 33 per cent. The upper limits occur at the age of 2 years in all save the South eastern, where 3 years is the age of highest relative mortality. In all regions ages 2, 3 and 4 show the most rapid decline, the greatest declines being at age 3 in the Northeastern group (28 per cent) and the South-eastern (25 per cent).

Accidents of all kinds are rapidly increasing in importance. Here is a class of accidents of which the causes are well known, the prevention relatively simple. Further emphasis must be placed on safety in the home, since in all probability, though the study does not so indicate, most of these accidents to children occurred in that sanctuary.

THE BRITISH MEDICAL ASSOCIATION AND THE VOLUNTARY HOSPITALS

Prior to 1920 the Voluntary Hospitals of Great Britain—purely charitable organizations supported by philanthropy for the benefit of the poor—admitted the majority of persons seeking hospital care. All who could not pay for the services of private physicians and who were unwilling to accept or were not entitled to service in the Poor Law Hospitals found the Voluntary Hospitals freely available. The Poor Law Hospitals were next in importance in providing hospital care for the poor. Patients, however, had to be "destitute" before they could be admitted to these institutions, although in a few areas service was given to practically any person belonging to the income classes entitled to participate in the National Health Insurance. Private patients were generally cared for in nursing homes, which formed but a small part of the hospital service for the nation.

In the decade after 1920, two fundamental changes took place in the traditional methods for providing hospital care in Great Britain. The first was the result of social and scientific developments, the second, of legislation. Following the World War, the increased demand for hospitalization, which everywhere is characteristic of modern nations, was overstimulated in England. One of the causes of this increased use of hospital care was the health insurance system, which furnished only a general practitioner service and left all the more serious cases to be cared for by hospital staffs. Much of the increased use of hospitals was due to the scientific advances in medicine, which introduced many new methods of diagnosis and treatment requiring institu-

1 Gafaer W. M. Time Changes in the Relative Mortality from Accidental Burns Among Children in Different Geographic Regions of the United States 1925-1932. Pub. Health Rep. 51: 1308 (Sept. 18) 1936.

5 California, Colorado, Idaho, Montana, Oregon, Utah, Washington and Wyoming.

tional equipment. As a consequence, the Voluntary Hospitals were overcrowded and their financial resources were exhausted.

The economic conditions following the World War had caused the wealthy and middle classes to decrease or suspend their gifts to Voluntary Hospitals, which were then forced to seek contributions from the industrial and low wage groups. To meet the financial crisis, two types of hospital plans were developed—contributory or “poor men’s” schemes, and provident or “middle class” schemes. A committee appointed to investigate the plight of the Voluntary Hospitals considered the inclusion of hospital service under the National Health Insurance but advised the extension of the contributory and provident schemes to provide the funds necessary to maintain the Voluntary Hospitals.

In the meantime Poor Law Hospitals with government assistance were developing a bed capacity twice that of the Voluntary Hospitals. Antagonism on the part of the poor toward Poor Law Hospitals was lessened because of improvement in facilities and the introduction of some free choice of physician. In 1929 the Local Government Act transferred these institutions to county and borough councils and by removing the “destitution” test threw them open to general service for the community. In fact, the regulations were such that these hospitals were opened to practically all the inhabitants of the administrative area in which they are located with the only stipulation that the patient be charged the cost of maintenance, subject to his capacity to pay.

The important effect of the appropriation of the Poor Law Hospital by the county or borough council was that the hospital became an integral part of the public health service under the supervision of the medical officer of health. As of April 1935, 42,082 general hospital beds had been appropriated by the local councils. In addition, a number of appropriations were made of children’s hospitals, municipal institutions, tuberculosis hospitals and others.

The change in the nature of the Poor Law Hospitals and the placing of power, responsibility and financial means in the hands of the local authorities will have an important effect on the future status of hospitals in England. The changed relations with the public are forcing changes in the attitude of the medical profession toward the hospitals. The Voluntary Hospitals were the training ground of the medical profession. In return for staff appointments, physicians rendered medical services without charge. Since the majority of the patients in Voluntary Hospitals are now paying, the British Medical Association recommends the introduction of pay beds and set forth the following policy.¹

Although the medical profession will gladly give, as always its services gratuitously to those who cannot afford to pay for them, it is inequitable to require it to give its services without

remuneration in voluntary hospitals which treat persons able to pay, and which in practice collect payments from a large number of their patients. The field of private practice has inevitably contracted, with the result that consultants, and in particular the younger consultants, are finding it increasingly difficult to secure and maintain a standard of living which represents a reasonable reward for their services and which enables them to maintain the highest possible standard of professional efficiency. In the view of the B. M. A. there should be remuneration of the medical staff in respect to all medical services in hospitals for which payment is made, directly or indirectly—by contributory schemes, local authority, employer or patient.

The British Medical Association has steadfastly maintained that the community will be served best if the hospital devotes itself exclusively to consultant and specialist service. Furthermore the association, in condemning the break in the relations between the general practitioner and the patient when the patient enters the hospital, urges the establishment of a new type of hospital called the “home hospital,” to be introduced where the treatment is such as can be given by a general practitioner but which for any reason cannot well be given in the home, these “home hospitals” to be staffed by local general practitioners. It also recommends that admission to a general hospital or to the outpatient department be only on the recommendation of a general practitioner.

With regard to the new Council Hospitals, provisions have been made to prevent encroachment on private practice. All medical officers appointed must be full-time officers and cannot engage in private practice. Thus the British Medical Association, believing that the voluntary hospital and the general practitioner form the keystone of all medical service, is striving to assure their continued existence in the interest of the public and the medical profession.

The medical profession and the hospitals in the United States may derive some guidance from the trend in England. What would happen to the general and special practitioners in the private practice of medicine and to private hospitals of the United States if county hospitals here were permitted to accept patients without any regard to their financial responsibility? Such a condition has actually threatened California in recent years. How long would it be before the limited practitioner became merely a salaried employee of lay boards in charge of county hospitals? What would become of the community investment in non-tax-supported or voluntary hospitals when the chiseling campaign of county controlled competition began? Is it worth while to alienate and destroy the sympathetic and charitable interest of the community in voluntary hospitals that obtains today? Who would maintain the quality of medical care and hospital practice if the medical profession, because of salaried positions and political red tape and regulations, became impotent to safeguard and advance the quality of the medical service? Perhaps economic manipulation of the voluntary hospitals is the first long step toward state managed medicine.

¹ The British Medical Association and the Voluntary Hospital Brit J supplement 1: 1647 (June 13) 1936

LOSS OF PROTEIN DURING FASTING

The animal body differs from a mechanical heat engine in that, during the life of the organism, there occurs constantly some oxidation of material with the production of heat whether or not fuel in the form of food is provided. As it is an old observation that the living organism can withstand deprivation of energy-yielding food for a considerable period, it follows that total inanition represents the withdrawal through combustion either of excess materials previously stored in the body or, in the absence of these, of substances entering into the essential structure of the body. The various aspects of the metabolism of fasting have been worked out from experimental studies both on human subjects and on animals. Following the withdrawal of food, the reserve carbohydrate in the form of glycogen is first used up, then the stored fat is called on as a source of vital fuel, with the result that in a starved animal the fat depots have been largely depleted. The nitrogen output representing the protein metabolized promptly falls to moderately low values, where it remains until the terminal rise. Since an appreciable output of nitrogen persists despite the lack of intake of protein, it is reasonable to believe that body protein is being metabolized. The particular source of this protein is significant.

An attempt to apportion to certain organs and tissues their relative and absolute shares in the total loss of protein from the body during fasting has been reported recently by Addis, Poo and Lew.¹ Two large groups of albino rats of similar age, sex and body weight were studied: one group was used immediately as a control and the second was subjected to analysis after a fast of seven days, during which only water was given. The total protein of the entire body and of most of the organs showed a decrease after the fasting period. The muscle, skin and skeleton together account for almost two thirds of the total protein lost from the body. Both the liver alone and the alimentary tract, pancreas and spleen together account for about one sixth of the total protein lost. However, when the proportion of their own protein lost by the various organs and tissues is calculated, the results are striking. In the course of a fast of seven days the liver lost 40 per cent of its protein, the alimentary tract 28 per cent, the kidney, blood and heart each about 20 per cent, the muscle, skin and skeleton together 8 per cent, and the brain 5 per cent. Although the muscle, skin and skeleton together lose only a small proportion of their total protein, these tissues account for the major part of the protein lost during the period of inanition because of their large relative mass in the body. On the other hand the liver, and to a less extent the kidneys, blood and heart, show a surprising decrease in the proportion of their own protein during inanition. The eyeballs, testes and adrenal glands lost no protein.

A subsequent determination of the loss from the liver after a fast of but two days showed that 20 per cent of the protein of this organ had disappeared. The observations thus indicate that so far as protein is concerned the liver "may be a storage depot for use in time of need." However, the conclusion is expressed that decrease in function and incipient atrophy may account for the observed loss from the heart, kidney and alimentary tract. In view of the relatively large loss of their protein shown by the liver, heart and kidneys, the teleologic suggestion that the organs most essential for life are spared in great emergencies may well be questioned.

Current Comment

CONSTITUTIONAL FACTORS IN DISEASES OF THE CARDIOVASCULAR-RENAL SYSTEM

In an address before the Medical Section of the American Life Convention last June, Pearl² advanced three lines of evidence bearing on the constitutional factor in cardiovascular-renal diseases. A study was made of the pedigrees of three families with reference to the incidence of cardiovascular-renal diseases. Each of these families showed considerably greater frequency of disease of this group than is found in the general population. This fact in itself establishes a presumption that heredity has played a part in determining the incidence of cardiovascular-renal disease in these families. Pearl also cites the differences in anthropometric measurements of cardiac and noncardiac patients, which has been reported elsewhere and previously commented on in these columns.³ Finally the relation between the general biologic constitution of the individual and the incidence of cardiovascular-renal diseases may be approached in still another way. In an analysis of the pedigrees of 640 patients taken without selection from the author's records, 285 had some form of cardiovascular-renal disease and 362 were completely free of any trace of these diseases. When the two groups were studied with regard to their general health, it was found that 72.9 per cent of the cardiovascular-renal patients had enjoyed good health up to the time of record but that 81.2 per cent of the other group had been similarly healthful. The difference in favor of the latter group is 3.7 times its probable error and therefore is probably significant statistically. The general picture that emerges, he believes, is that a group of patients with some form of cardiovascular-renal disease, when compared with a group of patients without any such disease, exhibit as a group a definitely lower level of vitality not only individually but also with respect to the immediate families. This lower vitality level expresses itself in various ways, such as by definitely poorer family health up to the time of record, by greater mortality in proportion to the number exposed in the kinship class, and by fewer total life years, experienced and expected.

Association News

RADIO BROADCASTS

The American Medical Association and the National Broadcasting Company present the second series of dramatized health broadcasts under the title *Your Health*. The first broadcast in the new series was the thirty-second dramatized cooperative broadcast under the title *Your Health*. The theme for 1936-1937 differs slightly from the topic in the first series, which was "medical emergencies and how they are met." The new series is built around the central idea that "100,000 American physicians in great cities and tiny villages, who are members of the American Medical Association and of county and state medical societies, stand ready, day and night to serve the American people in sickness and in health."

The program is on the Red network and Pacific network of the National Broadcasting Company.

It should be noted that a station may take the program, or not. If a local N B C station is not broadcasting the program *Your Health*, it is possible that the management may be induced to broadcast the program if it receives evidences of local interest. The committee on education or other appropriate committee of the local medical society might take this matter up with the station management and tender cooperation in giving the program local publicity.

The topics are announced monthly in advance in *Hygieia*, the Health Magazine, and three weeks in advance in each weekly issue of *THE JOURNAL*. Topics and speakers for the next three broadcasts are as follows:

October 20 Arthritis, Morris Fishbein M.D.
October 27, Help for the Hard of Hearing W. W. Bauer M.D.
November 3 Community Sanitation Morris Fishbein M.D.

The time of the broadcast is Tuesday afternoon at 5 o'clock eastern standard time (4 o'clock central time, 3 o'clock mountain time, 2 o'clock Pacific time).

Medical News

(PHYSICIANS WILL CONFER A FAVOR BY SENDING FOR THIS DEPARTMENT ITEMS OF NEWS OF MORE OR LESS GENERAL INTEREST SUCH AS RELATE TO SOCIETY ACTIVITIES, NEW HOSPITALS, EDUCATION AND PUBLIC HEALTH.)

CALIFORNIA

Pediatric Meeting—The Academy of Pediatrics, region IV, will hold its annual meeting at the San Francisco County Medical Society Building, San Francisco, October 22-24. Speakers will include:

Dr. Williams McKim Marriott, Hypoglycemic Syndrome in Childhood
Dr. John M. Rector, Acute Sepsis in Infancy
Dr. James F. Rinehart, Vitamin C in Rheumatic Fever
Drs. Samuel Hurwitz and Sidney N. Zuckerman, Cervical Adenitis Treated with X Rays
Earl F. Meyer, Ph.D., Neurotropic Viruses and the Diseases Caused by Them

Arrangements have also been made for a round table on the prophylaxis of communicable diseases and ward rounds to Stanford, University of California and Children's hospitals. Attendance at the Stanford-University of Southern California football game will conclude the meeting.

DISTRICT OF COLUMBIA

Society News—The Baltimore City Medical Society will present the program before the Medical Society of the District of Columbia, October 28. Speakers will include Drs. John T. King on "Recent Cases of Isthmus Stenosis of the Aorta", George H. Yeager, Treatment of Peripheral Vascular Disease by Passive Vascular Exercise, and Harry C. Hull, "Perforative Gastric and Duodenal Ulcers."

University News—Dr. Richard P. Strong, professor of tropical medicine, Harvard University Medical School, Boston, will deliver the Smith-Reed-Russell lecture at the George Washington University School of Medicine, October 22, on "The Dysenteries." Dr. Walter Schiller of the University of Vienna and Reuben Kahn, D.Sc., Ann Arbor, addressed the

students and faculty, October 1, on "Morphology of Ovarian Tumors" and "Immunity in Syphilis" respectively. Rudolph J. Anderson, Ph.D., New Haven, Conn., will conduct a seminar, October 23, on "The Chemistry of the Acid-Fast Bacteria."

Health at Washington—Telegraphic reports to the U. S. Department of Commerce from eighty-six cities with a total population of 37 million, for the week ended October 3 indicate that the highest mortality rate (184) appears for Washington and for the group of cities as a whole, 10.2. The mortality rate for Washington for the corresponding period last year was 14.5, and for the group of cities, 10.1. The annual rate for eighty-six cities for the forty weeks of 1936 was 12.2 as against a rate of 11.4 for the corresponding period of the previous year. Caution should be used in the interpretation of these weekly figures, as they fluctuate widely. The fact that some cities are hospital centers for large areas outside the city limits or that they have a large Negro population may tend to increase the death rate.

FLORIDA

Addition to Board of Health Building—Construction on a new three story addition to the State Board of Health Building, Jacksonville, was begun September 10. The addition will cost \$25,000.

Society News—Dr. Alvin J. Wood, St. Petersburg, addressed the Pinellas County Medical Society in St. Petersburg, August 21, on "Progress in Medicine."—At a meeting of the Tri-County Medical Association (Highlands, Hardee and DeSoto counties) in Wauchula, recently, Dr. Joseph Halton, Sarasota, discussed x-ray therapy.

GEORGIA

Society News—At a meeting of the Fulton County Medical Society in Atlanta, October 1, Dr. Madison Hines Roberts presented "A Study of Mastoid Infection in Children." A resolution was unanimously approved at a meeting of the society, September 17, proposing the construction of a new building for the Atlanta Academy of Medicine and Dentistry.

New Medical School Building—Construction began September 30 on a new building at the University of Georgia School of Medicine, Augusta, to house the departments of physiology and pharmacology and biochemistry. There will be space for an auditorium with a seating capacity of 350. The cost will be between about \$75,000, unequipped. The ground floor of the main medical school building has been renovated to house the department of pathology in the north end while the entire third floor is now occupied by the departments of anatomy and microscopic anatomy.

ILLINOIS

Society News—Physicians employed by the Illinois State Department of Public Welfare have organized the Physicians' Association "for the betterment of the medical service in the various state institutions." At a general meeting, September 16, Dr. John J. Madden, Kankakee, was chosen president and Dr. Joseph Marcovitch, Jacksonville, secretary.—At a meeting of the Lee County Medical Society, October 5, Dr. Archibald L. Hoyne, Chicago, discussed infantile paralysis.—The Will-Grundy County Medical Society was addressed at Joliet, October 7, by Dr. Abraham R. Hollender, Chicago, who read a paper on "Vasomotor Rhinitis—Evaluation of Therapeutic Procedures with Special Reference to Ionization."—Dr. Harry M. Hedge, Chicago, addressed the Carroll County Medical Society October 13 on "Dermatologic Conditions Seen by the General Practitioner."

Chicago

Sir Joseph Barcroft Gives Lectures—Sir Joseph Barcroft, professor of physiology, University of Cambridge, England, gave two lectures at the University of Illinois College of Medicine, September 29-30, his subjects were "The Genesis of Respiratory Movements" and "The Effect of the Composition of the Blood on Mental Properties."

The Billings Lecture—Dr. Henry A. Christian, Hersey professor of the theory and practice of physic, Harvard University Medical School, Boston, will deliver the third Frank Billings Lecture of the Thomas Lewis Gilmer Foundation of the Institute of Medicine of Chicago at a joint meeting with the Chicago Society of Internal Medicine, October 26, at the Palmer House. His subject will be "Edema, Diuretics, Diuresis."

Society News—The Chicago Roentgen Society was addressed, among others, by Dr. Stuart W. Harrington, Rochester, Minn., on "The Diagnosis and Treatment of Diaphragm-

matic Hernia"—Dr Louis K. Guggenheim St Louis, addressed the Chicago Laryngological and Otolological Society October 12 on "The Ontogenetic Approach to the Pathology of Deafness"—The presidential address was delivered before the Chicago Pathological Society October 12 by Dr Carl W. Apfelbach on "Modern Concepts of Cirrhosis of the Liver"—The Chicago Neurological Society was addressed October 15, among others, by Drs Isidore Finkelman and Daniel Haffron on "Observations on the Circulating Blood Volume in Schizophrenia, Manic Depressive Psychosis and Epilepsy"—Dr Max L. Folk, among others, will present a preliminary report on 'Paracentesis and Atropine in the Treatment of Optic and Retinal Atrophies' before the Chicago Ophthalmological Society, October 19—Dr Samuel W. Becker will discuss 'Relation of Allergy to Dermatology' before the Chicago Society of Allergy, October 19—At a meeting of the Chicago Pediatric Society, October 20 Robert H. Gault, Ph.D., Evanston, will read a paper entitled 'Enlarging the Usefulness of the Vibrotactile Senses'

INDIANA

Personal—Dr Henry C. Rogers Rockville, observed his ninety-second birthday August 16—Dr Hubert Gros Delphi, has been named secretary of the Delphi board of health, succeeding the late Dr William R. Quick.

New Headquarters for Society—An auditorium seating 500 and a permanent club room in the Antlers Hotel constitute the new home of the Indianapolis Medical Society. Members of the society and their wives and guests were given a tea by the hotel management, October 13, prior to the dinner meeting of the society, which was the first in its new home. At this dedicatory session Dr Virgil E. Simpson Louisville discussed the U. S. Pharmacopoeia. Drs John H. Warvel and Cecil L. Rudesill will read papers on insulin protamine before the society October 27, at a joint meeting of the society with the Methodist Hospital Staff Society, October 20, Dr Goethe Link, among others, will speak on diseases of the parathyroids.

IOWA

Tick Survey in Thirty-Five Counties—Financed by social security funds, a tick survey was carried on during July and August to determine the prevalence of the common dog tick and other ticks in different parts of the state and the percentage of ticks that harbor the spotted fever virus. The work was sponsored by the state department of health in cooperation with Carl J. Drake Ph.D., state entomologist and Ralph R. Parker, Ph.D., U. S. Public Health Service stationed at the Rocky Mountain spotted fever laboratory, Hamilton, Mont. Thirty-five counties including those from which one or more cases of the disease have been reported in the last three years, were studied. Among 800 ticks shipped to Montana, 359 were alive on arrival. These ticks representing thirty-one different localities in Iowa, were identified and tested for evidence of harboring the spotted fever virus or other infection. Twenty-four of the tests with guinea-pigs proved negative. Four of the tests were rendered void because the guinea pig 'died of an intercurrent infection or had some reaction which suggested infection'. One test showed the presence of tularemia infection; the ticks concerned were collected in Walnut State Park, Polk County Iowa a few miles from Des Moines. One test was incomplete at the time of the report, and the guinea-pig in the remaining test showed fever of undetermined origin. It is expected that further study may throw light on the percentage of ticks harboring the virus of Rocky Mountain spotted fever in this region.

LOUISIANA

Personal—Dr Raymond L. Gregory, formerly of Iowa City, has been appointed assistant professor of medicine at the Louisiana State University Medical Center, New Orleans, it is reported.

Graduate Teaching—The Louisiana State Medical Society is sponsoring graduate lectures in obstetrics in cooperation with the Louisiana State Board of Health. Financed by social security funds, the courses are given in each district for five consecutive evenings and consist of lectures, motion picture demonstrations, consultation conferences and general discussions. The first lectures of the series were given in Minden October 4-9 and the second in Ruston October 12-16. Subsequent lectures will be given as follows: Bastrop October 26-30, Hammond November 2-6, Natchitoches November 9-13, Opelousas November 16-20, Jennings November 30, December 4, Franklin December 7-11 and Donaldsonville December 14-18. Lecturers include Drs Joseph W. Reddock,

Arthur Caire, Philips J. Carter, Peter Graffagnino, Edward L. King and Walter E. Levy, all of New Orleans and Clifford R. Mays, Shreveport.

MARYLAND

Personal—Dr Humphrey Warren Buckler, since 1903 president of the Maryland State Tuberculosis Sanatorium Commission, was elected president, August 13, succeeding the late Charles H. Knapp.

Census of Crippled Children—A census will be made of crippled children in Maryland to diagnose their disabilities and to determine the need of statewide clinics, the plan to include hospitalization and after-care of children requiring assistance. Only children financially unable to pay for medical care will be eligible for the service, the selection of cases to be made jointly by the local welfare board and the family physician. The Medical and Surgical Faculty of Maryland has approved the program, which will be carried out by the Crippled Children's Service of Maryland (Board of State Aid and Charities).

Course for Training in Syphilis Control—The Johns Hopkins School of Hygiene and Public Health and the Johns Hopkins University School of Medicine, Baltimore, have entered into a joint arrangement with the U. S. Public Health Service whereby a limited number of public health personnel may secure special training for the control and clinical management of syphilis. According to the *Health Officer*, an elective course will be offered this year for students in the school of hygiene. In addition, the surgeon general of the health service will recommend six physicians who have been selected by state and local health officers for special training in venereal disease control. These graduate students will be admitted to a course in clinical syphilology and may be paid the regular fellowship stipend from social security allotments for personnel training. The university also offers one fellowship for a one or two year term at an annual stipend of \$1,800 without maintenance. The public health trainees will be assigned to duty in the syphilis clinic at the hospital. Dr Joseph Earle Moore, associate in medicine at the medical school, will direct the work.

MASSACHUSETTS

Graduate Courses—The fourth annual graduate extension course, presented in the various districts of the state under the auspices of the committee on postgraduate instruction of the Massachusetts Medical Society, has been opened. The chairmen and the courses are as follows:

Dr Howard M. Clute Boston Acute Abdominal Emergencies
Dr Sidney C. Wiggan Newton Anesthesia
Dr Frank R. Ober Boston Arthritis
Dr William P. Murphy Boston Blood Diseases
Dr Robert B. Greenough Boston Cancer
Dr Everard Lawrence Oliver Boston Dermatology and Syphilis
Dr Elliott P. Joslin Boston Diabetes
Dr Paul D. White Boston Heart Disease
Dr Frederick T. Lord Boston Disease of the Lung
Dr Donald Munro Boston Neurological Surgery
Dr Harry C. Solomon Boston Psychiatry
Dr Chester M. Jones Boston Stomach and Duodenal Ulcer

MICHIGAN

Personal—Dr Roy C. Lintner has resigned as physician at the state reformatory at Ionia and has been succeeded by his assistant, Dr Victor F. Kling. George F. Forster, Ph.D., professor of biology, Olivet College, has been appointed bacteriologist to the Michigan State Department of Health, he will be on a leave of absence from the college for one year it is reported.

Hospital News—The new Jackson County Isolation Hospital, Jackson, was formally opened August 2. It was erected at a cost of \$90,000. A new series of conferences for the general practitioner opened October 1 at the Receiving Hospital, Detroit. In addition to the usual one hour devoted to the clinical pathologic conference fifteen minutes will be given over to the presentation of the gross specimens from the necropsy material and operative clinic, and forty five minutes to a general clinic.

Changes in Health Officers—Dr Francis B. Carroll, Battle Creek, has been appointed health officer of Van Buren County. Dr Kurt C. Becker, Toledo, Ohio, has been named district health officer with headquarters at Royal Oak. He succeeds Dr Charles H. P. G. Benning. The appointment of Dr David Littlejohn, head of the health unit in Michigan, as health officer of Chippewa County, has been announced. Dr Lloyd H. Gaston, assistant health commissioner of Michigan, and Richland County, Ohio, has been placed in charge of district health unit 7 of the Couzens Foundation. His headquarters will be in Gladwin, succeeding Dr Eldred A. Tied-

MINNESOTA

Personal—Dr Cecil J Watson, Minneapolis, has been appointed associate professor of medicine at the University of Minnesota Medical School, Minneapolis, effective September 1.—Dr John A Malmstrom has resigned as health officer of Virginia to engage in private practice.—Dr Thomas E Broadie has been appointed superintendent of Ancker Hospital, St. Paul, succeeding the late Dr Seymour R Lee.

Society News—The Nicollet-Le Sueur and the Blue Earth county medical societies were the guests of the St. Peter State Hospital, September 2, Dr Alfred W Adson Rochester, discussed indications for sympathectomy in cases of essential hypertension.—The Minnesota Academy of Medicine was addressed in Minneapolis October 7 by Drs Arnold Schwyzer, St. Paul, on "Chordoma," and Samuel E Sweitzer and Carl W Laymon, "Severe Cutaneous Reactions to the Barbiturates".—Dr Chauncey N Borman will discuss "Roentgen Diagnosis of Spontaneous Internal Biliary Fistula and Gallstone Obstruction" before the Hennepin County Medical Society, October 21, and Dr Cyrus O Hansen, "Coutard Method of X-Ray Treatment." Dr Walter C Alvarez, Rochester, addressed the society, October 1 his paper was entitled "Helpful Hints in the Diagnosis of Puzzling Types of Indigestion."

MISSOURI

Society News—Dr Marriott T Morrison discussed "Treatment of Gonorrhea in the Male" before the St. Louis County Medical Society, September 23.—The South Central Counties Medical Society was addressed in Houston, August 6, by Drs Duff S Allen, St. Louis, on "Differential Diagnosis of Acute Abdominal Conditions" and Carliss Malone Stroud, St. Louis, "Allergy".—Dr Austin A Hayden, trustee, American Medical Association, Chicago, showed a motion picture film depicting the activities of the office of the Association at a meeting of the St. Louis Medical Society, September 15.

NEW JERSEY

Scarlet Fever Closes School—The grade school in Parsippany was closed September 30 by the Parsippany-Troy Hills Township Board of Health because of three cases of scarlet fever among the pupils, according to the New York Times. All other public gatherings were banned by the board of health.

Society News—At a joint meeting of the Bergen County Medical Society with the Bergen County Pharmaceutical Association in Englewood, September 29, Dr Arthur C De Graff New York, spoke on "How Can the Practicing Physician Know the True Therapeutic Value of Drugs Recently Introduced in Medicine?" and George C Schicks, PhC, assistant dean, New Jersey College of Pharmacy, Rutgers University, Newark, "Better Understanding of Official Medication".—Dr Herbert F Traut, New York, addressed the Hudson County Medical Society in Jersey City, October 6, on "Cardiac Complications in Pregnancy."

Progress on Medical Center at Jersey City—The cornerstone of the medical building of the Medical Center of Jersey City was laid by President Roosevelt, October 2. The ceremony marked the half-way point in the program financed by Jersey City, Hudson County and the Public Works Administration and designed to make the institution the third largest medical center in the United States. The medical building will be one of seven large structures of the skyscraper type and several smaller buildings. It will cost \$4,545,000 and is being erected on the site of the old Jersey City Hospital. Ultimately the Medical Center will have a capacity of 2,000 beds. Completed units include the surgical building, the staff house and the nurses' building and ground has been broken for a new eighteen story building to include the present six story medical unit and the twenty-three story surgical unit connecting wing. The Hudson County Tuberculosis Hospital, another unit, costing \$3,960,000 is complete except for furnishing and equipment. The Margaret Hague Maternity Hospital with facilities for 300 adults and 300 babies is also finished. The Out-Patient and Psychiatric Hospital financed by Jersey City and the PWA at a cost of \$2,500,000 and not yet under construction, is to be a ten story structure. The buildings are of steel skeleton construction, fireproof and of buff colored brick, with granite and terra cotta exterior trim. While the plan for the Medical Center originated in 1921 with Mayor Hague, who is still in office, the historical development of the center goes back to 1881, when a small hospital was erected by the city. A more modern hospital was built in 1906 and in 1917 the cornerstone was laid for a second building and two stories were added to the old building. With the subse-

quent influenza epidemic the hospital was enlarged to include a nurses' home. In 1929 the cornerstone was laid for the twenty-three story surgical building, the highest structure in Jersey City, the ten story Maternity Hospital, and the seven-story Nurses' home, which is both a training school and a residence.

NEW YORK

Foreign Licentiatees in New York—At a meeting of the New York State Board of Regents, September 21, it was voted that on applications filed after October 15 no license issued by a legally constituted board of examiners in any foreign country will be endorsed until the applicant shall pass the licensing examination prescribed by law or regents' rule.

Society News—Dr Carter N Colbert, New York, addressed the Medical Society of the County of Nassau Mineola, September 29, on "The Etiology and Treatment of Polyneuritis in the Alcoholic Addict."—Dr Earl D Osborne, Buffalo, addressed the Medical Society of the County of Albany Albany, September 30, on "The Part of the General Practitioner in the Syphilis Control Program."

New York City

Hospital News—A revised announcement of a lecture course in dental medicine at Mount Sinai Hospital gives the name of Dr Seth Selig as the lecturer for March 11, 1937, on "Relationship of Arthritis to Focal Infection" instead of Dr Robert K. Lippmann. The announcement was published in THE JOURNAL, September 26.

Brooklyn Cancer Institute Dedicated—The new Brooklyn Cancer Institute, a unit of King's County Medical Center, was dedicated with appropriate exercises, October 13. The institute is an independent clinical unit of the division of cancer of the city department of hospitals, with Dr William E. Howes as administrative clinical director. The five story brick building has been renovated with WPA funds and will provide accommodations for eighty-six patients, as well as treatment facilities, both radium and x-ray, for outpatients (THE JOURNAL, August 29, p. 721).

Endorsement of Proprietary Hospitals—Sixty-two of the sixty-nine proprietary hospitals in the city have been endorsed by the department of hospitals for conforming with city regulations requiring standards of physical equipment and clinical and nursing service. The seven institutions not complying with the department's regulations have minor changes to make before they will be approved. The regulations, effected about a year ago, require that a responsible medical board including members of the local county medical society, be set up by each institution. Each approved institution now has this board, as well as a registered physician licensed by the state. Since the inauguration of the regulations, five proprietary hospitals have gone out of existence.

Comprehensive Study of Suicide—The clinical and socio-psychologic phases of the problem of suicide will be investigated in a study to be carried out in the psychopathic division of Bellevue Hospital. The recently organized Committee for the Study of Suicide, Inc., cooperating with the commissioner of hospitals, and the director of the psychiatric division, has worked out a plan of research to be conducted by a special staff. The funds for the work have been contributed by the committee and will be administered by the New York University Medical College, which is affiliated for teaching purposes with Bellevue Hospital. The daily average of seventy-five psychiatric and alcoholic admissions will afford an unusually abundant source of material for special psychologic study. A trained psychiatrist will be in charge of the clinical studies. All data incident to the study will be recorded for use in training young psychiatrists and advanced medical students. It is planned to hold periodic staff meetings to apprise staff members of the progress of the investigation and the most important clinical observations made (THE JOURNAL, April 11, p. 1324).

OHIO

The Bunts Lecture—Dr Clay Ray Murray, associate professor of surgery, Columbia University College of Physicians and Surgeons, New York, delivered the Bunts Lecture at the Cleveland Clinic, October 6 his subject was "The Time Element in the Treatment of Fractures." The lecture is under the joint auspices of the clinic and the district fracture committee of the American College of Surgeons.

Pharmacy Exhibition—The history of pharmacy was depicted in an exhibit at the Cleveland Medical Library Auditorium October 16, presented under the auspices of the Northern Ohio Druggists Association, Academy of Pharmacy, School

of Pharmacy, department of pharmacology of Western Reserve University, Academy of Medicine and the Cleveland Medical Library Edward Kremers Ph.D., professor of pharmaceutical chemistry, University of Wisconsin, Madison, discussed "Source Material for History of the Apothecary Shop," and Dr James D Heard, professor of medicine, University of Pittsburgh, "Old Drugs in Old Jars"

Resolution Governing Medical Licensure—Graduates of medical schools in foreign countries applying for license to practice in Ohio must submit a complete transcript of all work done prior to graduation, according to a resolution adopted at a recent meeting of the Ohio State Board of Registration in Medicine. In case there is any difficulty in the evaluation of this material, the board shall require one year of internship in an approved hospital or one year of education in an approved medical school in the United States. Credentials of foreign applicants must be filed with the secretary of the board at least six months prior to examination

PENNSYLVANIA

Emergency Medical Relief Service Abandoned—Emergency medical relief service as it had existed in Pennsylvania since December 1933 was abandoned by the State Emergency Relief Board as of September 19. A special session of the state legislature this year appropriated for relief purposes a sum much less than the amount requested and also fixed inflexibly the proportion of the total that might be spent for administrative costs, it was explained. A delegation representing the Medical Society of the State of Pennsylvania, the state nurses' association, the state dental association and the state pharmaceutical association met with representatives of the relief board August 14 to ask a more gradual transfer of the relief medical service from state to local responsibility. Governor Earle chairman of the board, asked the delegation to appoint a representative to meet later with the board to confer on the problem. At the August meeting it was pointed out that the relief medical service as administered since December 1933 had maintained a low morbidity and mortality rate and an almost complete freedom from neglect of the sick. In the twelve months July 1935 to June 1936 with an average of 288,000 families on relief the average cost per relief case for all medical care was 97 cents

Philadelphia

Dr Elhason Appointed Professor of Surgery—Dr Eldridge L Elhason, professor of clinical surgery, University of Pennsylvania School of Medicine, has been appointed John Rhea Barton professor of surgery to succeed the late Dr Charles H Frazier. Dr Elhason was graduated from the University of Pennsylvania School of Medicine in 1905 and has been a member of the faculty since 1907 except for two years of army service during the World War. He became professor of clinical surgery in 1925 and was appointed to the same position in the Graduate School of Medicine in 1926. Dr Elhason is surgeon at the University, Presbyterian and Philadelphia General hospitals

Pittsburgh

Graduate Courses—The eleventh series of practical courses presented by the Allegheny County Medical Society, Harrisburg, is now under way. Dr Howard A Power opened the first course, October 9 on operative obstetrics. The remainder of the series is as follows:

Dr David B Ludwig Office Gynecology
Drs Eben W Fiske Harold W Jacox Paul L Jenny and Jessie Wright Principles and Practice of Physical Therapy
Drs Lawrence G Beinhauer and Bernhard A Goldmann Management and Treatment of the Syphilis
Dr Edmund R McCluskey Preventive Pediatrics Respiratory Disease in Infants and Children
Drs Charles Howard Marcy Leon H Hetherington and George W Hobson Recent Trends in the Treatment of Pulmonary Tuberculosis with Special Emphasis on the Use of Artificial Pneumothorax

TEXAS

Personal—Dr Robert J Rowe, Kaufman has been appointed a member of the state board of health to succeed Dr George W Cox, Del Rio, who resigned.—Dr Howard R Dudgeon Waco, president of the State Medical Association of Texas, was guest of honor at a dinner given by the McLennan County Medical Society in Waco September 8. Dr R. Spencer Wood president of the county society presided and speakers included the following former presidents of the state society: Drs Marvin L Graves and John H Foster Houston Samuel E. Thompson Kerrville, John O McRey-

nolds, Dallas and Don J Jenkins, Daingerfield.—Dr Lloyd B Sheffield has been appointed health director of the Dallas public school system succeeding Dr Edythe P Hershey, Austin, resigned. Dr Sheffield has been assistant health director for five years

Tri-State Meeting—The thirty-first annual meeting of the Tri-State Medical Society (Louisiana, Arkansas and Texas) will be held in Longview, Texas, October 26-27, under the presidency of Dr Dunbar R. Baber, Daingerfield. The speakers will include:

Dr Oscar M. Marchman Dallas The Paranasal Sinuses as Focus of Infection
Dr Willis C. Campbell Memphis Physiological Principles Applied to the Treatment of Fractures
Dr Henry M. Winans Dallas, Undulant Fever
Dr Charles A. Wyatt Marshall Toxemias of Pregnancy
Dr Robert H. Millwee, Dallas Radiation in Cancer Therapy
Mr E. M. McDermitt Dallas, Insurance Under Compensation Act.
Dr Walter L. Kitchens Texarkana The Isms and Pathosis of Medicine.
Dr Seale Harris Birmingham Relation of the Pituitary, Thyroid and Adrenal Glands to Hypo- and Hyperinsulinism.
Dr Ruy Carl Young, Covington La. Forced Perivascular Spinal Drainage, a Valuable Therapeutic Procedure in the Treatment of Chronic Epidemic Encephalitis
Dr Shelby B. Hinkle Little Rock Ark. Obstetrical Case Management.
Dr William Hibbitts, Texarkana Prostatic Resection.
Dr Leonce J. Kinsimsky, Texarkana Medical Economics
Dr Stanley George Wolfe Shreveport Newer Aspects in Diagnosis and Treatment of Congenital Syphilis

Dr Rosco G. Leland, Director, Bureau of Medical Economics, American Medical Association Chicago, will deliver the annual oration on "Economics and the Ethics of Medicine."

VIRGINIA

Personal—Dr Edward M. Parker, Emporia, was guest of honor at a dinner meeting of the Fourth District Medical Society in North Emporia. Dr Wright Clarkson, Petersburg was toastmaster and speakers included Drs James Morrison Hutcheson, Richmond, Cecil E. Martin, North Emporia, Rufus L. Raiford, Franklin, and Guy M. Naff, North Emporia.—Dr Nathan W. Stallard, Dungannon, recently completed fifty years of medical practice.

WEST VIRGINIA

Sanatorium Dedicated—A forty bed sanatorium for Ohio County was dedicated at Roney's Point, near Wheeling, September 17, during the annual meeting of the West Virginia Tuberculosis and Health Association. The building is 1,200 feet above sea level and is one story high with provision for a second story if necessary. It cost \$170,000, of which the county provided \$30,000, the Federal Public Works Administration \$43,384 and thirty-five citizens of Wheeling guaranteed the remainder, which is to be repaid by the county.

Society News—Dr Francis A. Scott, Huntington, addressed the Cabell County Medical Society, Huntington, September 10 on "Orthopedic Treatment of Arthritis."—Speakers at the meeting of the Kanawha Medical Society in Charleston, September 8 were Drs William R. Geraghty and William S. Love, Baltimore, on "Fractures of the Skull and Their Treatment" and 'Functional Heart Disease' respectively.—Dr William C. McCally, Cleveland, addressed the Monongalia County Medical Society, Morgantown, September 1 on "Infections of the Hand."—Dr Walter M. Simpson Dayton, Ohio addressed the Ohio County Medical Society, Wheeling, September 25, on "Progress in Artificial Fever Therapy."

WISCONSIN

State Survey of Venereal Disease—Surgeon Oliver C. Wenger of the U. S. Public Health Service recently completed a survey of the venereal disease activities of the Wisconsin State Board of Health. In his report to the surgeon general he records that the number of patients with dementia paralytica entering the state psychiatric hospital has decreased from 12 per cent in 1913 to 5 per cent in 1935. In 1915 31 per cent of the pupils in the state school for the blind became blind as a result of gonorrheal ophthalmia whereas in 1935 only three of 157 pupils were entered on this diagnosis. The state has thirteen clinics widely scattered and in communities where free facilities are not available indigent patients are treated by private physicians at the expense of the community. Free laboratory service is maintained by the state. A review of case records of the clinics and interviews with physicians, nurses and social workers showed a surprisingly small number of early cases, the report said in fact in only one clinic were any primary cases reported. Dr Wenger also pointed out that most patients remain under treatment and observation until they have received a maximum amount of treatment. Dr Wen-

ger emphasized the social hygiene program carried on in the schools and colleges since 1919 and attributed to it in great measure the success of the entire program. Two workers are employed full time in lecturing on social hygiene in the schools. In the calendar year 1935 the man worker made nearly 500 talks to a total attendance of more than 25,000 men and boys, the woman worker 265 talks to nearly 16,000 women and girls. Dr. Wenger recommended that the state board of health have on its staff a physician who would devote his full time to venereal disease control. He also suggested an advisory board made up of specialists in urology, syphilology, laboratory diagnosis and related fields, and the employment of more lecturers for the social hygiene program.

GENERAL

Academy of Physical Medicine—The Academy of Physical Medicine will hold its annual meeting at the Hotel Statler, Boston, October 20-22. The president, Dr. Frank H. Krusen, Rochester, Minn., will speak on "The Present Status of Physical Medicine." Dr. Stafford L. Warren, Rochester, N. Y., will present the Arthur H. Ring Foundation Lecture on "Fundamental Principles Concerned in the Treatment of Gonococcus Infections by Artificial Fever Therapy." Other speakers on the program will include Sir Robert Stanton Woods, London Hospital, London; Dr. William Benham Snow, New York; Dr. Abraham Myerson, Boston; Dr. Rebekah Wright, Boston; Dr. William J. Schatz, Allentown, Pa.; and Dr. William F. Roberts, minister of health, St. John, N. B.

Memorial to Dr. Ricketts—Funds are being solicited by Northwestern University to establish a foundation in memory of Dr. Howard Taylor Ricketts, who died in 1910 from typhus fever incurred in Mexico while engaged in a study of its mode of transmission. Dr. Ricketts graduated from Northwestern University Medical School in 1897. He served as fellow in dermatology at Rush Medical College. In 1903 he received an appointment as instructor and later as associate professor in pathology and bacteriology at the University of Chicago. In 1910, the year of his death, he accepted an appointment as professor of pathology at the University of Pennsylvania School of Medicine. Contributions to the fund which it is hoped, will total \$100,000, will be deposited with the trustees of Northwestern University for conservation and administration. The fund will be permanent, only the income to be utilized.

Association of American Medical Colleges—The forty-seventh annual meeting of the Association of American Medical Colleges will be held in Atlanta, Ga., October 26-27. The first days program will be as follows:

Dr. James N. Baker, Montgomery, Ala., Need for Closer Integration of the Agencies Interested in Medical Education and Licensure.

Edwin E. Reinke, Ph.D., professor of biology and secretary of the faculty, Vanderbilt University, Nashville, Liberal Values in Pre-medical Education.

Ralph J. Gilmore, Ph.D., professor of biology, Colorado Springs Liberal Arts Background for Medicine.

Dr. Frank L. Bahbott, Jr., New York, What Medical Colleges Expect Hospitals to Do to Continue the Education of the Intern.

Dr. Claude W. Munger, Valhalla, N. Y., Continued Education of the Medical Student During His Internship.

Tuesday's program will include a presentation of teaching objectives and methods in Emory University School of Medicine. Wednesday there will be a symposium on integration of the medical curriculum, presented by Drs. George S. Eadie, Durham, N. C.; William Boyd, Winnipeg, Manit.; Jonathan C. Meakins, Montreal, Que.; Edward W. Alton Ochsner, New Orleans; and Herman G. Weiskotten, Syracuse, N. Y.

American League Against Epilepsy—Members of the International League Against Epilepsy living in the United States or Canada have organized an American branch of the league with the following officers: Drs. William G. Lennox, Boston, president; Myrie G. Peterman, Milwaukee; and Temple S. Fay, Philadelphia, vice presidents; Frederic A. Gibbs, Boston, secretary; and Walter B. Cannon, Boston, vice president for America of the international league. The chief qualification for membership is an active interest in the problem of epilepsy or in the care and treatment of epileptic patients. Persons who are not physicians may be admitted up to 10 per cent of the membership. Dues which include membership in the international league are \$3.75 for four years. The next meeting of the American branch will be during the annual session of the American Medical Association in Atlantic City in June 1937. Interested persons should communicate with Dr. Gibbs, 910 Medical Building, Boston City Hospital, Boston. Dr. Lennox is president of the international league which will hold its next meeting with the International Neurological Congress in Copenhagen.

Sept 5 1936

The Treatment of Maxillofacial War Injuries

In 1932 the army council appointed a committee to report on the treatment of the wounds of the jaws and face that occur in modern warfare. Among the members of the committee were Sir Harold Gillies, the leading plastic surgeon in this country, Col. J. P. H. Helliwell, formerly commandant of the army dental corps, Mr. W. Kelsey Fry and Mr. W. Warwick James, dentists who have devoted special attention to this subject. The report, based largely on the experience of the great war, can be described as the last word on the subject. The matters investigated were (1) the provision and equipment of special hospitals or departments for maxillofacial injuries, (2) general methods of treatment and (3) the training of dental officers in the principles of preliminary treatment in the field. The committee assumes that it would be practicable to give only first aid until the wounded man has reached the main dressing station, which may not be for some hours. It makes the following recommendations:

PRELIMINARY TREATMENT

In the early stages, preliminary treatment would be restricted to life saving and would chiefly be the prevention of suffocation and the arrest of hemorrhage. Simple instructions should be given on these points to all men collecting the wounded. The danger of suffocation is most commonly due to loss of control of the tongue. As the result of the injury, this may occur to such a degree that the air passages are obstructed. Posture is then of vital importance and stretcher bearers should not lay the wounded man on his back but on his chest, with the head hanging over the end of the stretcher. He should be kept so until passed into medical care. If he is able to walk, he must stoop well forward till he comes under treatment. The committee emphasizes the importance of keeping the tongue well forward, by which stretcher bearers may save many lives. This will also tend to check hemorrhage, but it may be necessary to plug wounds external to the mouth and also to apply digital pressure. At the regimental aid posts and advanced dressing stations little can be done beyond treatment for shock and hemorrhage, but the tongue should be kept forward if necessary by a suture or clip. The throat should be examined and cleared of foreign bodies.

TREATMENT BY THE SURGEON

At the main dressing or casualty clearing stations the surgeons should correct as far as possible displacement of the hard and soft tissues and fix them as early as possible, but without undue tension. When much bone is lost the raw ends should be covered by mucous membrane if practicable and the advisability of sewing mucous membrane to the skin at the margin of the wounds should be considered if this can be done without tension. Catgut sutures are the best. This suturing greatly reduces the extent and difficulty of later plastic operations, but injudicious overapproximation (which occurred in the war) should be avoided. War experience showed a high frequency of abscess formation in the lower jaw, and therefore the surgeon should consider the advisability of sub-mandibular drainage at the outset by inserting one or more tubes.

TREATMENT BY THE DENTAL OFFICER

There are two main principles: (1) conservation of injured teeth and loose fragments of bone, (2) fixation of displaced fragments of jaw in correct position. The dental officer should be most conservative with regard to extraction of teeth, because

of their importance in the retention of appliances. The exposed pulp of fractured teeth should if possible be removed at once when the teeth may be valuable in subsequent treatment. Unless a tooth is actually involved in the line of fracture, it usually should not be disturbed. The retention of partly detached fragments of bone concerns both the surgeon and the dentist. The recuperative power of the fragments is usually good and as a rule none should be discarded. The slightest attachment of periosteum is justification for retention of a fragment. As long as teeth are present in the fragments and in corresponding region of the maxilla, the dental officer should immobilize the fragments in normal occlusion by interdental wiring. Even if the whole maxillary region is lost, the molar fragments should be held in normal occlusion by this means. During intratracheal anesthesia the throat should be well packed with gauze until the jaws are ready to be wired together. If necessary a long stout stitch should be passed through the dorsum of the tongue and the ends secured and left until the reflexes are recovered. Owing to the great mobility of the fragments, care is necessary when manipulating a gag. The mandible should be held forward and upward. When this procedure is not possible, owing to an edentulous fragment or corresponding maxillary region, fixation will be more difficult. If the patient has unbroken dentures, these may be used as splints assisted by external bandages. Impression composition or gutta percha may be molded inside the mouth to control the fragments. The surgical wiring of fragments is absolutely contraindicated in all compound fractures of the mandible. As a rule, fractures of the maxilla are simpler to deal with than those of the mandible. The fragments can be supported by the mandibular teeth with the aid of an external bandage. If the fracture is on one side, the sound side can be wired to the mandible. If possible, it is better to arrange a support independent of the lower teeth, such as the modified Kingsley splint.

Liability of Nursing Home for Contraction of Puerperal Fever

In the house of lords (the highest court in this country) an appeal was heard with regard to the liability of a maternity home for a patient contracting puerperal fever in it. The home was a small one, containing only sixteen beds, and was administered by the county council of Lindsey, Lincolnshire. Some of the beds were in single rooms, known as private wards, for which a weekly charge of \$21 was made. For the beds in the public wards the charge was \$10. The patients were attended by their own physicians, but the council provided the nursing staff. June 30, 1933 a woman was admitted and on July 4 she developed a high temperature. Her physician diagnosed appendicitis and she was removed to Grimsby Hospital. The ward in which she lay and the nurses in contact with her were disinfected. It subsequently was found that she was suffering from puerperal fever. When this was known at the home, another disinfection took place—on July 5. In cases of puerperal fever, swabs are taken of the throats of all persons in contact with the patient to ascertain whether any one is a carrier. In this case no swabs were taken, as it was thought that the disinfection would render this useless. July 9 another woman was admitted. She developed a temperature of 100.6 on the following day, after her confinement. Puerperal fever was diagnosed.

July 12 the respondent in this appeal arrived. She had arranged for a private ward, but none was available and she had to go into a public ward. Nothing was said about the previous cases. She was delivered July 13. On July 16 four patients and on July 17 the respondent developed puerperal fever. She was removed to the hospital. The home was then closed. She brought an action against the council on the grounds of (1) breach of contract in not giving her a private

room, (2) negligence of their servants in not closing the home before her admission, and (3) failure to inform her or her medical adviser of the case of puerperal fever. The appellants pleaded that there was no breach of contract on their part and no negligence on the part of their servants or agents and that their only duty to her was to provide a competent medical nursing staff for the home, which they did. The jury found that there was a breach of contract in not supplying a private room and a breach of duty in administration, because swabs of the throats had not been taken and information as to the case of puerperal fever was not given. They gave damages of \$3,750. The case was taken to the court of appeal, where the judgment in the lower court was affirmed. A further appeal was then made to the house of lords.

The lord chancellor in giving judgment for the respondent said that the jury was justified in thinking that without taking swabs there was a grave risk that a carrier might be present and that until this was eliminated it was dangerous to admit a new patient. It was contended that even if there was negligence the appellants were not responsible in law but that the responsibility rested on their health officers, who controlled the administration of the home. He was unable to accept that view. The appellants were carrying on a maternity home and were inviting prospective mothers to use it. They therefore owed a duty to them to make the premises reasonably safe or, if there was any hidden danger, of which they ought to have been aware, to give those invited due notice. Also they were responsible in law for the mistakes of their agents. It had been argued that it had been decided that where a public authority carried on a hospital it was not responsible for mistakes in medical treatment or nursing, provided reasonable care was taken in appointing competent nurses and physicians. This had no application to the present case. The respondents did not provide medical attendance and there was no complaint that the nurses were wanting in skill. The complaint was that the appellants invited the respondent to a home which they ought to have known was in a dangerous condition and did not inform her. When a corporation acted through an agent it was liable for his mistakes whether he was a physician or belonged to any other profession.

Lord Elibank Heads the Osteopathic "General Council"

The collapse of the osteopaths' attempt to obtain official registration in this country has been described in previous letters. They have now set up "A General Council of Osteopaths" to regulate the practice of osteopathy. Standards of education and training are to be laid down, the creation of institutes for teaching is to be fostered, and a register of osteopaths is to be compiled. Provision is to be made for two members of the medical profession and two scientists to sit on the council. Lord Elibank, who in 1934 introduced into the house of lords the bill to regulate osteopathy, which was rejected, is to be the first president. It has always been possible in this country to obtain the support of persons of high social position for irregular cults of all kinds.

Sodium Nitrite Poisoning

The first cases of fatal poisoning due to sodium nitrite in this country have occurred. The victims were a chemical worker, aged 44, his wife, aged 42, and her daughter by a former marriage, aged 5. They died within two hours of dining. It appears that sodium nitrite had been used in meals taken for common salt. The potatoes cooked for the dinner were noticed to be of a peculiar brown. The public analyst found in the organs evidence of sodium nitrite and of no other poison. He suggested that rhubarb which was eaten at the dinner would by its acidity quickly decompose the nitrite with evolution of toxic nitrous acid. It was supposed that the man

took away some nitrite from the works. The only use that he could have had for it was thought to be as a plant food. The poisoning of a family by sodium nitrite has previously been recorded in England, but all the affected persons recovered.

PARIS

Sept. 5, 1936

Organized Medicine Proposes to Aid State Social Program

At the last elections for members of the legislature, the Left parties, a combination of the Communists and the Socialists known as the "Front populaire," obtained the majority of votes. The new secretary of public health is making a laudable effort to improve health conditions in general and rural sanitation in particular. He has welcomed the aid of organized medicine in carrying out his program of extension of the benefits of preventive medicine to all classes of citizens. In the August number of the bulletin of the *Confédération des syndicats médicaux*, an organization which represents all the regional syndicates or societies aiming to look after the relations of organized medicine to the public, the question of the part to be taken by members of these societies in the proposed preventive medicine measures is discussed in detail. A circular sent to all physicians first quotes a resolution passed by the "syndicat" of the department of the Seine, in which Paris is situated, to the effect that "organized medicine is ready to assume technical responsibility, by collective contract for the organization and functioning of preventive medicine." Two methods have been proposed to fulfil this obligation: first, to appoint four or five medical officers for each department (there are eighty-six in France), who shall be responsible for all branches of preventive medicine, such as periodic health examinations preliminary or not to training for competition in sports, vaccinations, antepartum and nursing consultations, and so on. The other method is to confide the entire administration of the law to the local "syndicats" or county (departmental) medical societies, the latter being granted a certain sum annually by the government, which could be distributed to such members as had taken part in carrying out the provisions of the law.

The circular explains that only preventive medicine and not actual care of the sick or injured is to be regarded as constituting the duties of those who aid in the preventive medicine work. This means that most loyal cooperation on the part of all volunteers will be necessary if the profession is to take advantage of showing what organized medicine can do. It is proposed to begin the work in only a small number of departments, so as to ascertain what local modifications will be necessary.

In the collective contract between the "syndicats" and the secretary of public health, it is proposed to establish health centers in every city and smaller community, in which complete physical examinations will be carried out, these centers to serve also with the aid of specialists and laboratories as diagnostic agencies. Owing to the rapid development of the interest in sports in France, all those who wish to participate shall be obliged to be examined at regular intervals. Prophylactic vaccinations (variola, diphtheria, tetanus) are to be noted in a book to be kept by every schoolchild. Other duties of these public health centers are to give antepartum advice and examination and consultations for nurslings and infants, all of the latter also being recorded in a book to be kept by mothers. Every child and adolescent will be given a "livret de sante" or health record, in which all types of examinations will be noted. How practical it will prove to be for local medical societies to take charge of all these public health duties remains to be seen.

The Causes of Road Accidents

Some interesting statistics appear in the June Bulletin of the French Union of Tourist Associations. There are 2,075 first aid stations distributed over all the automobile highways of France. In spite of the rule that gives priority to a machine on the right when two automobiles have occasion to cross, the number of accidents remains higher than it ought to be. One reason is that speed regulations are seldom observed here. Motorcycle policemen who watch for speeders are almost unknown in France. In the 1935 statistics of the union, failure to observe the code (priority belongs to the machine on the right) and lack of prudence caused 50.9 per cent of the accidents. Next in order of frequency came skidding on dry roads 14.9 per cent, unknown causes 8.36 per cent, attempts to pass another car during the day 6.95 per cent, skidding on wet roads 6.51 per cent, bad condition of machine 6.19 per cent, faulty lighting or visibility 6.19 per cent, trying to pass another car at night 2.39 per cent, and physiologic (!) causes 1.88 per cent.

When the various modes of locomotion are considered, the accidents during 1935 can be placed in the following groups: automobiles 51.66 per cent, bicycles 20.86 per cent, motorcycles 11.38 per cent, pedestrians 7.15 per cent, unclassified 2.81 per cent, horses 1.38 per cent and airplanes 0.02 per cent. This second statistical study shows that in proportion to their number, more accidents were due to bicycles and motorcycles than to any other form of transport.

Results of 1,256 Sympathectomies

The surgery of the sympathetic nervous system is of comparatively recent date, hence the report of 1,256 operations made by Leriche and Fontaine at the June 10 meeting of the *Académie de chirurgie* is of interest. The largest number of operations were 273 on the cervical sympathetic, 178 lumbar sympathetic, 61 resections of the presacral nerve and 574 periarterial sympathectomies. The mortality has been minimal, one death in the 273 cervical and 3 per cent for the lumbar sympathectomies. The utmost precautions must be taken in operating on patients who have chronic infected ulcerations or a localized gangrene, by local disinfection, and prophylactic drainage. In cases of angina pectoris, good results can be obtained in 70 per cent of the cases, provided the coronary obliteration be not too far advanced. In three cases of megacolon, satisfactory results were obtained by combining removal of the superior and inferior mesenteric plexus with a bilateral lumbar sympathectomy. The relief of painful disorders of the extremities does not always follow a periarterial sympathectomy alone. It is often necessary to associate this operation with one on the "neurogliome" and on the *rami communicantes*. Vasomotor and trophic lesions, Raynaud's disease, scleroderma, chronic edemas, painful posttraumatic osteoporosis, delayed consolidation and chronic varicose and "essential" ulcers are cured in an impressive number of cases. Spasmodic paralyses can be greatly relieved by sympathectomy. The same is true for hyperhidrosis. An arteritis should never be treated by periarterial sympathectomy unless the vessel is permeable, i. e., not obliterated. If such should be the case, an arterectomy should be combined with a sympathectomy. Resections of the popliteal and posterior tibial arteries are to be done with much caution. In case of obliteration of these vessels, only a lumbar sympathectomy should be performed. In thromboangitis, arterial resection and lumbar sympathectomy have given approximately the same, i. e., 55-58 per cent, good results. In this disease more lumbar sympathectomies than arterial resections were performed. In sclerosing arteritis the reverse was the case, the good results attaining a percentage of 76.4 per cent. The surgery of the sympathetic nervous system has a definite place but in order for it to be efficacious the indications must be well established and a thorough knowledge obtained of the physiopathology.

Only Drug Stores May Sell Medicinal Preparations

The French senate has just passed a bill making it a misdemeanor punishable by a fine of from \$2 to \$60 for the first and double for the second offense for any establishment other than a drug store to sell preparations which possess curative or preventive properties. This also applies to medicinal plants, which are sold at present in large quantities by department stores and street vendors.

Obligatory Antitetanus Vaccination in French Army

A study of the efficacy of vaccination against tetanus made by a committee appointed by the Academy of Surgery revealed that the incidence of tetanus following injury was considerably less in those who had had prophylactic injections of antitetanus serum. This report has made such an impression in military circles that the secretary of national defense, M. Daladier, has just issued an order making vaccination against tetanus obligatory for every soldier, as is antityphoid vaccination and that against variola.

International Congress of Hepatic Insufficiency

A large number of medical meetings at which all nations will be represented form an important part of the program for the world's fair of 1937 to be held in Paris. The Congress on hepatic insufficiency is to hold its meeting at Vichy Sept. 16-18, 1937, under the presidency of Prof. Maurice Loeper of Paris. The congress includes two sections, one on medicine and biology and one on medical treatment and hydrology. The secretary is Dr. J. Aimard, 24 Boulevard des Capucines, Paris.

Obstetrician Promoted in Legion of Honor

An amply merited honor has just been conferred on Professor Couvelaire, head of the Clinique Baudelocque at Paris. He was named a Commander of the Legion of Honor, an order founded by Napoleon, as a recognition of distinguished service to France.

Treatment of Adenopathy Secondary to Cancer of Tongue

A report of work at the Curie Foundation was made by A. Tailhefer at the June 24 meeting of the Académie de chirurgie. Of 110 cases of removal of the lymph nodes secondary to a cancer of the tongue performed between 1923 and 1931, eighty-four cases were selected for a study of end results dating back from five to twelve years since operation. In one of these eighty-four the primary neoplasm was a doubtful papilloma with normal lymph nodes. The other eighty-three cases were all positive for cancer on microscopic study. As a rule, the operation was done about three weeks after cessation of the Curie therapy of the tongue, being carried out on one side of the neck and including the submaxillary lymph nodes and those along the sternocleidomastoid and internal jugular vein. This was followed by application of radium over the cervical region in all cases in which microscopic examination revealed the existence of cancerous changes in the excised nodes. This was true of sixty-nine of the eighty-three cases. Nineteen of the eighty-three in which there was secondary lymph node involvement were cured. Among the sixty-four in which the operation was a failure are included three postoperative deaths, four deaths from intercurrent disease during the first five years after treatment and four deaths from probable recurrences in which the seat of the latter could not be determined. In nineteen cases of lymph node recurrence the tongue remained cured. Ten of these nineteen recurrences were on the operated side, on the opposite side and three bilateral. In thirteen cases there was a recurrence of the cancer in the tongue but none in the cervical lymph nodes. In fifteen others recurrence took place in the tongue, mouth and neck

and in six there were distant metastases. The author emphasized the necessity of thorough removal of all lymph nodes even though the primary lesion in the tongue is minute. The operation should be performed as soon as possible after completion of the radium treatment of the tongue and should include both sides of the neck in all cases in which the primary lesion extends beyond the midline of the tongue. Radium treatment of the cervical lymph nodes is of no avail in curing a postoperative recurrence.

Search for Tubercle Bacilli in Broncho-pulmonary Suppuration

At the June 23 meeting of the Académie de médecine an example of how modern methods of search for tubercle bacilli have permitted the detection of the tuberculous character of pulmonary lesions when least suspected was presented by Professor Bezançon and Drs. Braun and Meyer. Tubercle bacilli were found in the expectoration of patients in whom the usual radiographic and clinical evidences of tuberculosis were present. The association of acid-resistant bacilli to the bacteria found in cases of abscess and gangrene has been known for some time. The use of the Loewenstein technic as modified by Saenz and Costil combined with the Petragram culture medium has enabled the authors to find tubercle bacilli far more frequently than ever before. In four cases of pulmonary abscess and in one case of bronchiectasis a routine search by cultures of the sputum revealed tubercle bacilli. Staining methods had been positive in only one of the five cases. A number of similar cases, observed by other internists here, were also cited. Couve, in a thesis published in 1933, showed that an active tuberculosis often appeared during the course of or following pulmonary suppurations. Lemierre is of the opinion that the bacilli in a latent often minute tuberculous lesion are set free as the result of the abscess formation. Only systematic search by the culture method will reveal the presence of tubercle bacilli when the principal disease has a different etiology. In the discussion, Sergent believed that the explanation offered by Bezançon and his associates seemed the most plausible one, viz., that the bacilli in a latent tuberculous lesion were liberated by the suppurative process but that one must also consider the possibility that prolonged suppuration weakens the resistance to such an extent that a latent focus becomes active.

International Gastro-Enterologic Congress During the Paris Exposition

The International Gastro-Enterological Society has just arranged its second meeting. The first sessions will be held at Paris, September 13, 15 and 17, 1937, under the presidency of Prof. Pierre Duval of Paris. The questions to be discussed are (1) the early diagnosis of cancer of the stomach and (2) acute and chronic obstruction of the small intestine. The former will form the subject of papers by French and German internists. The French contributions embrace the surgical aspects, Professors Duval and Gosset, the clinical and enterologic aspects Professor Carnot, roentgenology, Dr. Guttman, gastroscopy, Dr. Moutier, gastroscopic photography, Dr. Gann, chemical diagnosis, Professor Labbe, pathologic histology, Dr. Bertrand, and operative diagnosis, Drs. Gatellier and ChARRIER.

Professor Konjetzny will present the report of German participants aided by Professor von Bergmann (medicine), Professor Buerger (chemical diagnosis), Professor Saverbruch (surgery), Professor Berg (roentgenology), Professor Henrici (gastroscopy and gastroscopic photography), and Professor Staemmler (pathologic histology).

The second sessions will be held at Vichy, Sept. 16-18, 1937, and the subject will be hepatic insufficiency. Many participants from foreign countries will take part in this meeting.

Aug 17, 1936

The Klein Reaction for the Diagnosis of Cancer

With the exception of the Freund-Kaminer reaction, no previously known serologic examination method for malignant tumors has been able to make any claim of specificity. As early as 1910 Freund and Kaminer were able to establish that the serum of noncancerous persons destroys cancer cells, whereas that of cancer patients has no such ability. They believed that cancerous persons offered a special protection for the carcinoma cells. A qualification applies, to be sure, as carcinoma serum is able to protect carcinoma cells but not sarcoma cells confronted with lysis. Waterman believes in the validity of these observations and in the predisposition to cancer also assumed by Freund and Kaminer, a tendency probably manifested by the disappearance of the carcinolytic substance.

G Klein too, in discussing the technic of serologic diagnosis, takes as his point of departure a disturbance in the ability of the organism to defend itself against cancer, and this defect may be termed equivalent to the creation of a predisposition to cancer. Klein improved the Freund-Kaminer cytolytic reaction as well with reference to the widening of its applicability (so that it is immaterial which type of malignant tumor is in question, carcinoma or sarcoma), as likewise with reference to the exact evaluation of the test in both positive and negative directions. Klein substituted for the cell suspension from human tumors used by Freund and Kaminer in carcinolysis a similar cell suspension from an adenocarcinoma in the mouse. Since the Freund-Kaminer reaction follows in a number of other diseases the same course as in cancer and likewise presents difficulties in the technic of its carrying out, it has been found insufficient for diagnostic needs and cannot be of practical significance. Klein was the first to effect a thoroughgoing improvement of the Freund-Kaminer reaction with regard to its specific character so that the correct percentages of cancer positive and cancer-negative tests could be increased to numbers far in excess of the results obtainable by any other reaction test. The reliability of the criteria and the technic were perfected by Klein in such a way that subjective factors were prevented from influencing the observation of the reaction.

Although the data accumulated to date have ripened into a high percentage of accurate results, the latter have, however, as yet no absolutely uniform character. To effect follow-up examination of the previous significant and promising observations, the national bureau of health entered into collaboration with the Cecilienhaus of Berlin-Charlottenberg, an institution that has under its surveillance an extremely large number of cancer patients. A Pickhan, E. Haagen and W. Imhäuser have recently reported this helpful undertaking in the *Reichsgesundheitsblatt*.

In the Klein reaction the exclusion of a group of disturbing factors is to be borne in mind, particularly those of an endogenic or exogenic nature, since they may exert a profound biologic influence on the entire organism as well as on the composition of the blood serum and consequently on the result of the reaction. The troublesome factors that do not permit an examination of the blood serum till they have been removed are (1) nonsterile withdrawal of blood, (2) withdrawal of blood when the patient is not fasting, (3) removal of blood within twenty-four hours after narcosis, after the administration of narcotics, anesthetics, hypnotics an excessive amount of alcohol, insulin, thyroxine and sodium chloride infusion, after blood transfusion and so on, (4) withdrawal of blood within from six to eight days following cessation of bleeding in more severe cases of external or internal hemorrhage (5) withdrawal of blood during fever of above 38 C (100.4 F), (6) withdrawal of blood within fourteen days after illumination and within ten weeks after irradiation, and (7) cachexia.

The survey extended over a year and included more than 500 serums of cancer patients, also patients presenting other diseases and normal persons. Hematologic specimens were sent to Professor Klein for examination without notation of the clinical diagnosis, as "blind tests." Chronologically the examinations are divided into three sections, each of which was considered separately: section 1 from December 1934 to May 1935, section 2 from May 1935 to July 1935, and section 3 from July 1935 to February 1936.

Section 1 comprises 309 cases all told. In attempting a critical analysis of the material, eighteen cases (5.85 per cent) were eliminated from consideration a priori on the basis of Klein's list of disturbing factors. These modifying influences have to do with either incomplete fasting during the withdrawal of blood, cachexia, hemorrhages, operations or irradiation during the susceptible period. Accordingly, 291 cases remained to be evaluated. Because the degree of correspondence between the clinical determinations and the serologic diagnoses was not clear in seventy cases (22.6 per cent of the total), these cases were eliminated from consideration pending further investigation. Thus finally the number of cases actually analyzed was reduced to 221 (71.52 per cent). As serologically correct, 146 cases (that is, 66 per cent of 221 cases and 47.25 per cent of 309 cases) could be diagnosed, seventy-five cases (that is, 33.94 per cent of 221 cases and 24.26 per cent of 309 cases) could be diagnosed as serologically incorrect. Among the seventy cases temporarily set aside, one case, that of a clinically undefined pulmonary tumor, was considered as in a class by itself. In nineteen cases the first interpretation was later changed. With the inclusion of these sixty-nine clarified cases, 290 specimens of serum were used for the final evaluation. The serologic diagnoses corresponded with the clinical observations in 182 cases (62.76 per cent), in 108 cases (37.24 per cent) there was, on the other hand, a lack of agreement. This section showed the extraordinary importance of the various disturbing factors for the observations as a whole.

In section 2 a number of cases were grouped together on the basis of even more painstaking investigation. These cases were able to hold their own against any objective criteria with reference to the proper preparation of the patients, exclusion of all modifying influences and the employment of the correct technic for withdrawal of the blood (the last named of especial importance for the final result). Of the fifty-eight cases in this group, fifteen had by reason of disturbing influences to remain without consideration in the evaluation. Three other specimens were set aside pending further clinical determinations. Thus there remained forty cases. Of these, thirty were evaluated as correct-positive, six as correct-negative and four as incorrect-negative. This means a result of 90 per cent accurate evaluations (if one is to reckon these small figures in percental terms).

In section 3 there were examined serums from patients presenting malignant tumors, eighty-two cases, serums of persons not presenting tumors, sixty-seven cases, total, 149 cases.

Of the serums of eighty-two tumor patients, seventy-nine yielded a correct-positive serologic reaction, three cases an incorrect reaction. Of the cancer cases, 96.3 per cent were accordingly correctly evaluated. Of the serums of sixty-seven persons not presenting malignant tumors, sixty-four exhibited a correct-positive serologic reaction and three an incorrect-positive reaction. Accordingly 95.5 per cent of the cancer-free serums were correctly diagnosed. Four cases as not free from modifying influences and six cases pending further investigation had to be set aside. The final figures for section 3 with the foregoing ten cases deducted is as follows: serums of patients presenting malignant tumors, seventy-six cases, serums of patients not presenting tumors, sixty-three cases, total, 139 cases.

Of the seventy-six tumor serums, seventy-four reacted correct-positive and two incorrect-negative. Accordingly, 97.4 per cent of the malignant tumors were correctly diagnosed from the serum.

Of the sixty-three serums of persons not presenting tumors, sixty-two showed correct-negative and one incorrect-positive reactions. Of the cancer-free specimens, 98.4 per cent were correctly evaluated. The mean of accurate diagnosis of the serums of both cancer patients and cancer-free persons amounted thus to 97.8 per cent.

These gratifying results in section 3 could have been obtained only through the strictest observance of directions and exclusion of all unduly influenced cases. This survey had at its disposal a larger selection of case material than could have ordinarily been obtained in practice. On the other hand, a considerable amount of fluctuation, particularly toward the unfavorable side, must be reckoned with and this is due to the greater incidence of the disturbing influences outlined. This is probably all the more frequently the case when the serums are assembled by persons lacking an absolutely uniform point of view.

The Klein cancer reaction is thus able, as Pickhan and his collaborators conclude, to function as Klein himself had claimed it would, with reference to both positive and negative evaluation or, in other words, for the determination of the presence or absence of cancer. However, the restricted selection of cases and the precautionary measures instituted with regard to the withdrawal of blood had to be most rigorously observed. These prerequisites are, however, extremely far reaching and greatly restrict the practical applicability of the method, the more so since the withdrawal of blood can take place only at the hospital. Withdrawal of the blood specimen by a practicing physician must therefore as a rule be rejected.

To what extent the Klein cancer reaction can succeed in being of general significance in the practice of medicine can be determined only after a further extensive collection of data, since in the foregoing material all diagnoses of cancer and other conditions had already been determined either clinically, histologically or roentgenologically. No single cases had therefore been detected by serologic reaction alone. Then too, it has yet to be determined whether the Klein reaction can provide an early diagnosis and whether it can be used as an indication of cure subsequent to operative or radiation therapy.

A recent issue of the *Münchener medizinische Wochenschrift* contains an account of various clinical investigations with this Klein cancer reaction. The Würzburg Surgical Clinic has made a two year study (under Dr Reimers) of this procedure and carefully prepared no less than 691 blood specimens. As the controls showed, the reaction here too presented the same percental numbers of correct results. The "blind test" procedure being followed. A number of specimens were eliminated because of the impossibility of carrying on the clinical observation over a sufficiently extended time, several cases were also obscure. Of the remaining 628 cases, 181 by reason of the modifying factors could not be statistically evaluated. In the end there actually remained 438 cases incontestably established both clinically and histologically. Of the cases in this group correct diagnoses were made in 411 instances by the Klein test. The proportion of accurate results amounted on the average to 93.7 per cent.

Above 84 per cent of malignant tumor cases were correctly diagnosed. Among these, six cases of recurrence after radical operation were accurately recognized whereas of twenty-two carcinoma cases not previously treated only nineteen, that is, 86.5 per cent, exhibited correct positive reactions. The sarcoma cases presented less favorable results of twenty-eight cases (that is 92.9 per cent) of benign tumors twenty-six were correctly detected as negative. Likewise virtually all other types of tumors, struma or hypertrophy of the prostate, for

example, showed correct-negative reactions. It was concluded from these results that by the Klein test it is possible to differentiate malignant and benign tumors with a greater certainty.

In the Second Medical Clinic of the German University at Prague, as reported by Dr Gröger, the test was performed on ninety patients in whom the presence of malignant neoplasms was regarded as a possibility. After elimination of all influenced cases, sixty-eight cases remained as material for evaluation. In 92.6 per cent of these cases the reaction found was proved by the further clinical course to have been correct. This corresponds favorably with the results obtained at the other clinics. Finally the Surgical Clinic of Munich had undertaken a more protracted investigation, which Dr Hepp discusses. Some 700 blood specimens in all were sent in to Professor Klein and some 200 of these were submitted "blind" namely, without any information as to the nature of the sickness or the case history. Specimens to which intentionally falsified information was appended were also submitted. The result showed that an average accuracy of 90 per cent could still be maintained. The open group (that is, the serum specimens that were accompanied by data) yielded 93.4 per cent correct diagnoses, the "blind" group 90.2 per cent. Both carcinoma and sarcoma cases reacted positively. Differentiation of benign and malignant tumors succeeded in a large majority of cases. It was especially noteworthy that hypertrophy of the prostate could be distinguished from carcinoma of the same organ in a high percentage of instances. All things considered, the Klein reaction seems to represent a forward step, any definite estimate of its worth must await further research and discussion.

Early Arising from Bed After Operations

The question of the best time for a patient to quit his bed in the postoperative period has been to the fore. In 1935 Paschoud of Lausanne in particular established a definite "earliest time." Professor Flörcken, surgeon, of Frankfurt has meanwhile undertaken large scale observations of the same subject. Excepting in special cases of infection, of heart disease or of exophthalmic goiter, Flörcken had all his patients who had undergone operations out of their beds on the day of the intervention or, at most, from one to two days afterward. The patients were permitted to sit in easy chairs or to go about in the room. If increased temperatures unrelated to bronchitis were exhibited, the getting up was for the time being postponed. A principal presupposition for early quitting of bed is that the operation shall have run a smooth course. A protective dressing of elastic material should be applied after abdominal and hernial operations and a plaster-of-paris dressing, according to the Böhler method, following intervention in the soft parts. These appliances must be placed in such a way that they do not inhibit ambulation.

The results of 219 abdominal and hernial operations performed on patients above the age of 30 (under diverse types of anesthesia and narcosis) were as follows. Of five fatal cases advanced carcinoma was present in four, of three patients who died of embolism, two presented inoperable carcinoma. One patient died of pulmonary embolism sixteen days after an operation for severe appendicitis with peritonitis. Indeed this patient presented particularly complicated pathogenic conditions and had already previously been afflicted with an embolism. Cancer patients, especially if bedfast prior to the operation, were not permitted to leave their beds very early thereafter. The rest of the patients recovered completely without complications. postoperative pneumonia was not observed in a single instance.

Early postoperative arising offers according to Flörcken's investigations a whole series of benefits. The procedure dispels the feeling of illness in a remarkably short time, the functions of the bladder and of the intestine that otherwise frequently

require artificial assistance are for the most part spontaneously reestablished. At the same time the hospital staff is spared additional burdens. Especially remarkable was the rapid recovery and uneventful convalescence of three patients who had undergone operations for severe scar hernias. Early postoperative arising means earlier discharge from the hospital and subsequent resumption of normal activity.

The Death of Professor Vulpius

Oscar Vulpius, emeritus professor of orthopedics at Heidelberg, was killed in an automobile accident at the age of 69. Vulpius was known as one of the founders of the modern German orthopedic school. Particularly noteworthy among his many valuable contributions to orthopedic surgery were the operative methods devised by him for the surgery of the tendons and joints and for tendon implantations. In addition to his published work on orthopedic therapy, Vulpius made numerous useful contributions to the literatures of the care of the deformed and of the treatment of poliomyelitis. His teachings on the technics of orthopedic surgery have likewise exercised a widespread influence.

Marriages

HENRY FRANKLIN GLENN JR., Gastonia, N C, to Miss Mary Jean Smith of Sylacauga, Ala, in Montreat, recently.

ROBERT JAMES McCLURE to Miss Phyllis H. Gratton, both of New Haven, Conn., at Charlevoix, Mich, August 19.

SOLOMON B MEYERSON St. Charles, Ill, to Miss Ida Edith Fisher of Long Branch, N J, in Chicago August 2.

ELIAS SMITH FREY, Louisville, Ky, to Miss Eloise Brown of Concord, Ga., in Atlanta, Ga, September 16.

LOUIS AUGUSTINE GIULIANO, South Norwalk, Conn, to Miss Mary Frances Dono of Brooklyn, August 2.

DONALD L. BORGES, Gowrie, Iowa to Miss Helen B. Guenther of Sandusky, Ohio, September 20.

ROBERT SALINGER to DR. WINIFRED S. HULL, both of New Haven, Conn., in Brewster, N Y, July 23.

EARL LEWIS CLAY, Oxford, N C to Miss Nell Smith Armistead of Nathalie, Va, September 9.

HENRY C. ROSENSTIEL, Freeport, Ill, to Miss Mildred Mershon of Mount Carroll, August 15.

BENJAMIN ANDERSON STRICKLAND JR., to Miss Lue Anne Massie, both of Baltimore, July 18.

WILLIAM H. M. ERB, Sassamansville, Pa, to Miss Sara Anne Smith of Hazleton, July 6.

JOHN M. WHITNEY, Jennings, La, to Miss Georgiana Rita Burst in New Orleans, August 1.

SALVATORE MEGNA, Milwaukee, to Miss Glendora Christensen of Two Rivers, Wis, July 15.

JOSEPH D. GATTI to Miss Mary B. Bartelucci, both of Hackensack, N J, August 1.

KENNETH EUGENE POWELL to Miss Doris Elizabeth Appell, both of Galva, Ill, October 3.

WILLIAM HENRY LACEY, Charleston, S C, to Miss Dick Dennis of Pinopolis, July 26.

RICHARD PETER NEARY to Miss Winifred Rita O'Reilly, both of Minneapolis, September 5.

HAROLD E. HAYMOND Perry, Iowa, to Miss Isabel Crawford of Minburn, September 16.

ARTHUR BRUCE GILL to Miss Mabel Halsey Woodrow, both of Philadelphia, August 3.

KINLOCH NELSON to Miss Alice Magill Deford, both of Richmond, Va, July 23.

JAMES BLISII McBEAN to Miss Grace Agnes Callan, both of Chicago, August 19.

EDWARD W. MENCHER to Miss Nadine Greenman, both of New York, August 9.

RICHARD B. NELSON to Miss Vera Prior, both of Hammond, Ind, July 25.

WILLIAM O. OTT, Fort Worth, Texas, to Miss Merle Gaither, July 17.

Deaths

Howard Lombard Beye ☉ Iowa City, Iowa Rush Medical College, Chicago, 1911 since 1927 head of the department of surgery and since 1924 professor at the State University of Iowa College of Medicine, associate professor from 1920 to 1924, assistant professor from 1917 to 1920 and instructor in surgery from 1914 to 1917, in 1913 assistant in medicine at his alma mater, served during the World War, member of the American Surgical Association, the Western Surgical Association and the American Association for Thoracic Surgery, fellow of the American College of Surgeons, attending surgeon to the University Hospitals aged 50, was killed, September 29, in an automobile accident.

Arthur Van Harlingen, Bryn Mawr Pa, University of Pennsylvania Department of Medicine, Philadelphia, 1867, chief of skin clinic at his alma mater, from 1871 to 1883, professor of dermatology from 1883 to 1895 and emeritus professor from 1895 to 1912 at the Philadelphia Polyclinic, formerly clinical lecturer at the Jefferson Medical College, Philadelphia, past president of the American Dermatological Association, for many years on the staff of the Children's Hospital, author of "Handbook of the Diagnosis and Treatment of Skin Disease," in 1884, which was published in four editions, aged 90, died, September 23.

William Duffield ☉ Los Angeles, University of Pennsylvania Department of Medicine, Philadelphia, 1893, member of the House of Delegates of the American Medical Association in 1932, at one time vice president, and councilor of the Second District, California Medical Association past president of the Los Angeles County Medical Society past president and secretary of the Southern California Medical Association past president, vice president and trustee of the Barlow Medical Library, member of the staffs of the Clara Barton Hospital and the California Lutheran Hospital, aged 69, died suddenly, September 9.

Edward Jonathan Klopp ☉ Philadelphia Jefferson Medical College of Philadelphia, 1906, also a pharmacist, professor of surgery at his alma mater, member of the Western Surgical Association, fellow of the American College of Surgeons, member of the medical advisory board of Philadelphia, during the World War, and until 1930 a member of the U S Naval Reserve Force aged 56, consulting surgeon to the Girard College, attending surgeon to the Delaware County, Pennsylvania and Memorial hospitals and the Jefferson Hospital, where he died, September 19, as the result of subacute bacterial endocarditis.

Arthur Parker Butt Sr ☉ Elkins, W Va, College of Physicians and Surgeons, Baltimore, 1895 past president and secretary of the West Virginia State Medical Association past president and secretary of the Barbour-Randolph-Tucker Counties Medical Society fellow of the American College of Surgeons, medical superintendent and owner of the Elkins City Hospital, aged 65, died, August 5, of coronary thrombosis.

Manfred Call ☉ Richmond, Va, Medical College of Virginia, Richmond, 1899, professor of clinical medicine and formerly dean at his alma mater member of the medical staff, Stuart Circle Hospital, one of the founders of the Children's Memorial Clinic, member of the staff, outpatient service, Memorial Hospital, aged 59, died September 13, in the Johns Hopkins Hospital, Baltimore, of bronchiogenic carcinoma.

Charles Arthur Zeigler, Amboy, Ill, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1908, member of the Illinois State Medical Society, president of the Lee County Tuberculosis Society, for many years a member of the board of education, aged 68, died July 6 of occlusion of the coronary artery.

Juan L. Payawall, Ramsey, N J, University of Maryland School of Medicine, Baltimore, 1917 member of the Medical Society of New Jersey, served during the World War formerly member of the board of health aged 41, died, July 27, in St Joseph's Hospital Paterson of acute appendicitis, general peritonitis and postoperative hemorrhage.

Elisha Hall Gregory Wilson ☉ Cape Girardeau, Mo, Washington University School of Medicine 1905, past president and secretary of the Cape Girardeau County Medical Society served during the World War, on the staff of St. Francis Hospital, aged 56, died, July 12, in the Missouri Baptist Hospital, St. Louis.

Benjamin Edward Twitchell Jr ☉ Assistant Surgeon Lieutenant (j g) U S Navy, Parris Island, S C., University of Illinois College of Medicine, Chicago, 1931, entered the navy in 1930, aged 32, died, July 25, in the Naval Hospital, of fracture of the cervical vertebrae caused by diving into a shallow swimming pool

Edward Milton Brown ☉ Chicago, Northwestern University Medical School, Chicago, 1893, clinical professor of surgery, Loyola University School of Medicine, fellow of the American College of Surgeons, senior surgeon to the Mercy Hospital, aged 67, died, September 28, of coronary embolism and chronic myocarditis

Louis Dwight Robertson, Malone, Texas, University of Arkansas School of Medicine, Little Rock, 1912, member of the State Medical Association of Texas past president of the Hill County Medical Society, aged 67 died, July 10, of hydro-nephrosis of the left kidney, aneurysm of the ascending aorta and cystitis

S M Shankle, Hollandale, Miss (licensed in Mississippi in 1882), member of the Mississippi State Medical Association, mayor of Hollandale, formerly member of the state legislature, aged 74, died, July 9, in the King's Daughters' Hospital, Greenville, following an operation for a ruptured appendix

Oscar Paul Schnetzky, Princeton, Wis., Milwaukee Medical College, 1903, College of Physicians and Surgeons of Chicago, School of Medicine of the University of Illinois, 1904, served during the World War, aged 57, died, July 28, in St. Agnes Hospital, Fond du Lac, of carcinoma of the pancreas.

Daniel Capron Norton, Manchester, N H., Dartmouth Medical School, Hanover, 1907, member of the New Hampshire Medical Society and the New England Otological and Laryngological Society, on the staffs of the Elliot and Balch hospitals, aged 55, died, July 14, of cerebral hemorrhage.

Erik Theophile Sandberg, Cardinal, Va., University of the South Medical Department, Sewanee, Tenn., 1899, member of the Medical Society of Virginia, served during the World War, aged 62, died, July 10, in the Elizabeth Buxton Hospital, Newport News, of intestinal obstruction

Lois Whitford Torres ☉ Mount Pleasant, Mich. University of Michigan Medical School Ann Arbor, 1929, school physician at the State Central Teachers' College aged 44, died July 25, in Panama City Fla., of a lesion of the spinal column involving the central nervous system

Daniel Erwin James, Holly Springs, Ark. College of Physicians and Surgeons, Dallas, Texas, 1908, Georgia College of Eclectic Medicine and Surgery Atlanta 1910 at one time member of the state legislature of Louisiana, aged 69, died, July 30, in a hospital at Shreveport, La

Albertus B Poppen, Muskegon, Mich. Rush Medical College, Chicago, 1909, member of the Michigan State Medical Society, fellow of the American College of Surgeons, aged 55 head of the gynecologic department of the Hackley Hospital, where he died, July 10, of heart disease

Cameron Carpenter Tallman, Fairfield Iowa Rush Medical College, Chicago, 1900, member of the Iowa State Medical Society, formerly county coroner on the staff of the Jefferson County Hospital aged 61, died August 1, in Fresno, Calif of arteriosclerosis and hypertension

William Edward McClanahan, Baltimore University of Maryland School of Medicine, Baltimore 1902, for many years a member of the city health department served during the World War, aged 57, died July 23, in the U S Marine Hospital of chronic myocarditis

Charles A Evans, Bluffs Ill. Medical College of Indiana Indianapolis, 1896 past president of the Scott County Medical Society, past president of the village board and member of the local board of education aged 67, died July 5 of myocarditis and diabetes mellitus

Alfred Olm Ellison, Chicago Hering Medical College Chicago 1911 member of the Illinois State Medical Society served during the World War on the staff of the Norwegian American Hospital aged 49 died July 29, of an overdose of morphine, self administered

John Fremont Leavitt, Collingswood N J University of the City of New York Medical Department, 1882 member of the Medical Society of New Jersey for many years health officer of Camden aged 77 died July 22, of arteriosclerosis myocarditis and nephritis

Raymond Henry Stenger, Marion Ind. Indiana Medical College School of Medicine of Purdue University Indianapolis,

1907, served during the World War, formerly on the staff of the Veterans Administration Facility, aged 53, died July 8 of coronary thrombosis

Frank Aldis Torrey ☉ Lake City, Mich., Northwestern University Medical School, Chicago, 1932, also a pharmacist mayor of Lake City and county coroner, on the staff of the Mercy Hospital, Cadillac, aged 54, died suddenly, July 11, of coronary occlusion

James Raymond Cahill ☉ Otisville, N Y., University and Bellevue Hospital Medical College, New York, 1916, at various times health officer of the town of Mount Hope and the village of Otisville, aged 42, died, July 8, of splenic infarction and myocarditis

Lavord L Lee, San Antonio, Texas, Birmingham (Ala) Medical College, 1902 member of the State Medical Association of Texas and counselor of the Fifth District, member of the city board of health, aged 58, died, July 4, of an accidental gunshot wound.

William Fletcher Walling, Binghamton N Y., Long Island College Hospital, Brooklyn, 1903, member of the Medical Society of the State of New York aged 66, died July 11 at his summer home in Heart Lake, of coronary occlusion and arteriosclerosis

Manning Alonzo Rountree, Reidsville, Ga., University of Georgia Medical Department, Augusta, 1892, member of the Medical Association of Georgia, formerly mayor of Adrian, and state senator, aged 69, died, July 21, in a hospital at Savannah

Horace Phillips, Philadelphia University of Pennsylvania Department of Medicine, Philadelphia, 1889, served during the World War, member of the Department of Mental Diseases Pennsylvania Hospital, from 1894 to 1913, aged 69, died, July 23

Henry Miller Goodman, Louisville, Ky., University of Louisville Medical Department, 1883, member of the Kentucky State Medical Association, formerly professor of chemistry and toxicology at his alma mater, aged 74, died, July 11

Rees Philpott, Middleport Ohio, Western Reserve University School of Medicine, Cleveland, 1920, member of the Ohio State Medical Association, aged 44 died, July 1, in St. Joseph's Hospital, Parkersburg, W Va., of cerebral hemorrhage

Everett F Long ☉ High Point, N C., Medical College of Virginia, Richmond, 1909, at one time health officer of Wake and Davidson counties, for many years on the staff of the Burrus Memorial Hospital, aged 58, died, July 5

Henry Ford Haskins, Peoria, Ill., St. Louis University School of Medicine, 1916, member of the Associated Anesthetists of the United States and Canada, served during the World War, aged 43, died, July 25, of pneumonia

Louise Marie Gerber-Dietmeier, Jasper Minn University of Minnesota Medical School Minneapolis, 1893 member of the Minnesota State Medical Association aged 67, died July 2 in a hospital at St Peter, of pneumonia

Jefferson Newton Hoyt, San Antonio Texas Keokuk (Iowa) Medical College, College of Physicians and Surgeons 1904, served during the World War aged 60, died July 23 in Des Moines, of chronic myocarditis

Leroy Thomas Telford, Alma, Ill. University of Illinois College of Medicine, Chicago, 1936, aged 26 died, July 12 in the Evangelical Deaconess Hospital, St Louis of an injury received by diving into shallow water

Charles Andrew Tignor, Washington, D C., Howard University College of Medicine Washington, 1901, a medical inspector in public schools aged 60, died, July 12 of prostatic obstruction infection and hemorrhage

Frank Scott Glover, Houston, Texas Atlanta College of Physicians and Surgeons 1910, member of the State Medical Association of Texas served during the World War, aged 49 died July 25 of coronary thrombosis

Lineus Wayne Fishel, York, Pa. Jefferson Medical College of Philadelphia 1920, member of the Medical Society of the State of Pennsylvania aged 40 died suddenly, July 20 of acute dilatation of the heart

John Knox, Davenport Iowa University of Pennsylvania Department of Medicine Philadelphia 1877 formerly mayor, school director and health officer of Princeton, aged 83 died, July 14 of chronic myocarditis

George J Rivard Sr., Assumption Ill. Chicago Medical College 1881 member of the Illinois State Medical Society aged 76 died July 8 in St. Mary's Hospital Decatur of acute pancreatitis and uremia.

John Edgar Hubble, Pomona, Calif., University of Virginia Department of Medicine, Charlottesville, 1891, member of the California Medical Association, aged 72, died, July 30, of coronary thrombosis

John Edwin Dougherty, Elkins, W. Va., Medical College of Virginia, Richmond, 1924, member of the West Virginia State Medical Association, aged 38, died suddenly, July 16, of coronary thrombosis

Maximilian Allen Richter, Buffalo, University of Buffalo School of Medicine, 1907, member of the Medical Society of the State of New York, aged 76, died, July 28, of cardiovascular renal disease

James Levi Lee, Auburndale, Fla., Cleveland College of Physicians and Surgeons, Medical Department of the University of Wooster, 1882, aged 80, died, July 27, of uremia and chronic nephritis

Joseph Emmor Pears, Decoto, Calif., Kansas City (Mo.) Medical College, 1902, at one time health commissioner of Pueblo, Colo., aged 73, died, June 23, of cerebral hemorrhage and arteriosclerosis

Merritt Matthew Gibson, El Paso, Texas, Ohio State University College of Medicine, Columbus, 1929, aged 34, died, July 8, in the Masonic Hospital, of myocarditis and pulmonary tuberculosis

George Joseph Roy, Brunswick, Maine, Laval University Faculty of Medicine, Quebec, Canada, 1891, aged 73, died, July 1, of arteriosclerosis, cerebral hemorrhage and bronchopneumonia

Dalton Yancy Rosborough, Palatka, Fla., Medical College of the State of South Carolina, Charleston, 1919, aged 46, died, July 3, in St. Luke's Hospital, Jacksonville, of angina pectoris

Sebastian B. Du Bose, Bishopville, S. C., University of Nashville (Tenn.) Medical Department, 1901, aged 59, died, July 10, in the McLeod Infirmary, Florence, of hemorrhagic colitis

Henry M. Strickland, Live Oak, Fla., Hospital Medical College, Atlanta, 1910, member of the Florida Medical Association, aged 48, died suddenly in July, at his camp on Blue Lake

Lawrence Daniel Roche, New York, Fordham University School of Medicine, New York, 1913, member of the Medical Society of the State of New York, aged 47, died, June 27

Gratten Almer Ehret, Cleveland, Western Reserve University Medical Department, Cleveland, 1890, past president of the board of education of East Cleveland, aged 69, died, July 30

Lewis Daniel Hammond, Irvins Store, Ky., University of Louisville (Ky.) Medical Department, 1895, member of the Kentucky State Medical Association, aged 66, died, July 11

Robert John Lawlor, Cleveland, Cleveland College of Physicians and Surgeons, Medical Department Ohio Wesleyan University, 1901, aged 64, died, July 14, of coronary sclerosis

Fred Bryce Jewett, Melrose, Mass., Harvard University Medical School, Boston, 1892, medical superintendent of the Reeves Sanatorium, Melrose Highlands, aged 69, died, July 26

William Edward Redford, Plainview, Texas, Louisville (Ky.) Medical College, 1893, member of the State Medical Association of Texas, aged 70, died, July 18, of pneumonia

Harold Earl Dodge, Franklin Park, Ill., Rush Medical College, Chicago, 1890, for many years health officer of Franklin Park, aged 73, died, July 13, of carcinoma of the prostate

David Alfred Baker, Glendale, Calif., Keokuk (Ia.) Medical College, College of Physicians and Surgeons, 1907, aged 54, died, July 19, at Sawtelle, of hypertensive heart disease

Louis Oscar Lesieur, Biddeford, Maine, Albany (N. Y.) Medical College, 1895, at one time member of the board of health of Rumford, city physician, aged 67, died, July 26

Jesse Thomas Nugent, Virgil, Kan., Washington University School of Medicine, St. Louis, 1909, aged 52, died, July 6, of cholecystitis with gangrene of the gallbladder

John Walter Telford, Margaretville, N. Y., New York Homeopathic Medical College, 1886, at one time postmaster of Margaretville, aged 72, died, July 21, in New York

George Nelson Manning, Wheaton, Ill., College of Physicians and Surgeons of Chicago, 1894, aged 66, died, July 13, in St. Charles Hospital, Aurora, of cerebral hemorrhage

Joel Henry Greene, Urbana, Ill., University of Buffalo College of Medicine, 1875, aged 84, died, July 29, in the Burnham City Hospital, Champaign, of angina pectoris

Silas Cicero Holloman, Caldwell, Texas, Memphis (Tenn.) Hospital Medical College, 1900, member of the State Medical Association of Texas, aged 55, died suddenly, July 2

Charles Valentine Pease, Tolland, Conn., Tufts College Medical School, Boston, 1904, aged 60, died, July 12, in Northampton, Mass., of hypertensive heart disease

David J. Walter, St. Louis, St. Louis College of Physicians and Surgeons, 1906 and 1914, member of the Missouri State Medical Association, aged 62, died, June 21

Louis J. Giers, Jerseyville, Ill., St. Louis College of Physicians and Surgeons, 1891, member of the Illinois State Medical Society, aged 69, died, July 11, of arteriosclerosis

Winfield Scott Moon, Audubon, Iowa, Barnes Medical College, St. Louis, 1899, aged 60, died, July 16, in the Clarinda (Iowa) State Hospital, of cerebral arteriosclerosis

Frederick A. Mandeville, Summit, N. J., New York Homeopathic Medical College and Hospital, 1888, aged 73, died, July 15, of chronic myocarditis and nephritis

Lyman R. Palmer, New Rochelle, N. Y., Hahnemann Medical College and Hospital, Chicago, 1880, aged 78, died, July 11, of chronic nephritis and arteriosclerosis

Charles F. North, Beaver Dam, Wis., Universität Leipzig Medizinische Fakultät, Saxony, Germany, 1884, aged 82, died, July 30, of senile dementia and arteriosclerosis

William Eugene Sloat, Denmark, Iowa, Long Island College Hospital, Brooklyn, 1873, Civil War veteran, aged 94, died, July 18, in Ottumwa, of arteriosclerosis

Henry Pilgrim Holt, Torrance, Pa., College of Physicians and Surgeons, Baltimore, 1886, aged 72, died, July 12, in the Torrance State Hospital, of lobar pneumonia

William A. Hays, Birmingham, Ala., Medical College of Alabama, Mobile, 1887, aged 77, died, July 16, in the Norwood Hospital, of carcinoma of the stomach

Francis E. Rohan, Joplin, Mo., Missouri Medical College, St. Louis, 1893, served during the World War, died, July 12, of coronary arteriosclerosis and cholecystitis

Setrac G. Eghian, New York, Medizinische Fakultät der Friedrich-Wilhelms-Universität, Berlin, Prussia, Germany, 1899, aged 60, died, July 30, of carcinoma

William J. Humphrey, Union City, Pa., University of Buffalo School of Medicine, 1890, also a pharmacist, aged 75, died, July 28, of cerebral arteriosclerosis

John Kemper Johnson, Boaz, Ala., University of Nashville (Tenn.) Medical Department, 1884, aged 74, died, in July, at Hot Springs National Park, Ark.

Julian Theodore William Kastendieck, Brooklyn, New York Homeopathic Medical College and Hospital, 1888, aged 71, died, July 7, of pernicious anemia

John L. Slaught, Hot Springs National Park, Ark., Arkansas Industrial University Medical Department, Little Rock, 1889, aged 79, died, July 4

Irvine White Patton, Ajo, Ariz., University of Virginia Department of Medicine, Charlottesville, 1895, aged 64, died, July 1, of chronic myocarditis

Dudley B. Channell, Oakland, Calif., Willamette University Medical Department, Portland, Ore., 1894, aged 81, died, July 9, of coronary occlusion

Richard Gregory Rozier, Lumberton, N. C., University of Maryland School of Medicine, Baltimore, 1899, aged 67, died, July 1, of myocarditis

William Petty, Wilkes-Barre, Pa., Long Island College Hospital, Brooklyn, 1886, aged 75, died, July 5, of cerebral hemorrhage due to a fall

John Miles Gathright, Oxford, Miss., Memphis (Tenn.) Hospital Medical College, 1898, aged 64, died, July 17, of myocarditis and nephritis

John Franklin McCarty, Richmond, Mich., University of Maryland School of Medicine, Baltimore, 1896, aged 64, died, July 14, of heart disease

Douglas Caulkins, Knoxville, Tenn., Hahnemann Medical College and Hospital of Philadelphia, 1886, aged 78, died, July 15, of myocarditis

Augustus Stanfield, Orange, N. J., Howard University College of Medicine, Washington, D. C., 1912, aged 45, died, July 1, of nephritis

Edward Day, Covington, Ky., Cincinnati College of Medicine and Surgery, 1888, aged 80, died, July 12, of heart disease and chronic nephritis

Hilton Hammond, South Bend, Ind., Hahnemann Medical College and Hospital, Chicago, 1887, aged 76, died, July 28, of cerebral hemorrhage

Robert J. McCready @ Pittsburgh, Bellevue Hospital Medical College, New York, 1873, aged 86, died, July 20, of cerebral embolism

Sandom Sidney Pace, Lee Park, Pa. (registered in Prothonotary's office in Luzerne County), aged 94, died, July 1, of arteriosclerosis

William Medill Bair, Des Moines, Iowa, Ensworth Medical College, St. Joseph, Mo., 1886, aged 80, died, July 5, of cerebral hemorrhage

Henry C. Simpson, Springfield, Ill., St. Louis Medical College, 1874, Civil War veteran, aged 92, died, July 13, of heat prostration

Arthur Alexander Rock, Milwaukee, Milwaukee Medical College, 1902, aged 60, died, July 17, of hypertensive cardiovascular disease

John Moore Delo, Philadelphia, Medico-Chirurgical College of Philadelphia, 1909, aged 61, died, July 15, of cardiac decompensation

Galen C. Paxton, Santa Monica, Calif., Louisville (Ky.) Medical College, 1883, aged 81, died, June 23, of coronary arteriosclerosis

Henry C. Fowler, El Dorado, Ark., Meharry Medical College, Nashville, Tenn., 1909, aged 55, died, July 25, of gastro-enteritis

Nimrod Edgar Underwood, Red Bay, Ala., Chattanooga (Tenn.) Medical College, 1900, aged 67, died, June 19, of septic arthritis

John Streeter Sidley, Los Angeles, Northwestern University Medical School, Chicago, 1906, aged 57, died, July 23, of pneumonia

Archibald C. Kennel, St. Louis, Missouri Medical College, St. Louis, 1887, aged 75, died, July 10, of cerebral hemorrhage

Joseph C. Hudspeth, Sandoval, Ill., American Medical College, St. Louis, 1882, aged 81, died, July 13, of heat exhaustion

Lester Dale Rickey, Columbus, Ohio, Ohio Medical University, Columbus, 1903, aged 59, was found dead, July 15, of myocarditis

John Llewellyn Hamilton, Leavenworth, Kan., Columbus Medical College, 1881, aged 81, died, July 13, of arteriosclerosis

Marion A. Young, Abbeville, La., University of the South Medical Department, Sewanee, Tenn., 1895, aged 62, died, June 4

Dee W. Kirby, Gurdon, Ark., Memphis (Tenn.) Hospital Medical College, 1904, aged 55, died, July 17, of heart block

John Paul Sullivan @ Omaha, John A. Creighton Medical College, Omaha, 1916, aged 55, died, July 14, of sunstroke

James Henry Stokes, Erin, Tenn., Vanderbilt University School of Medicine, Nashville, 1881, aged 77, died, June 14

Burton J. Dodge, Alma, Neb., Keokuk (Iowa) Medical College, 1898, aged 59, died, July 8, of chronic nephritis

Vernon B. Cosby, Maplewood, Mo., Homeopathic Medical College of Missouri, St. Louis, 1883, aged 80, died, July 14

Joseph D. Cunningham, Fairfield, Mich. (licensed in Michigan in 1905), aged 84, died, July 12, of arteriosclerosis

Adolphus A. Hicks, Muldrow, Okla., Memphis (Tenn.) Hospital Medical College, 1899, aged 71, died, July 28

William F. Flack, Knoxville, Tenn., Knoxville Medical College, 1910, aged 51, died, July 8, of angina pectoris

John W. Dalton, Dalton, Ark., American Medical College, St. Louis, 1880, aged 80, died, July 24, of pneumonia

Thomas W. Harper, Ruston, La., Memphis (Tenn.) Hospital Medical College, 1892, aged 85, died, July 1

W. A. Briggs, Memphis, Tenn. (licensed in Tennessee in 1909), aged 75, died, July 28, in Knoxville

Daniel Hill Sneed, Normandy, Tenn. (licensed in Tennessee in 1910), aged 60, died, July 10

T. George Burge, Judsonia, Ark. (licensed in Arkansas in 1903), aged 63, died, June 19

Robert J. Ferguson Carter, Tenn. (licensed in Tennessee in 1904), aged 70, died, July 11

Cornelia E. Brown, New York, Columbus Medical College, 1887, aged 73, died, in July

Bureau of Investigation

GLANRAY AND PROSTAL-RAY

Prostatic Gland Devices Declared Fraudulent and Debarred from the United States Mails

Glanray, Glanray Corp., Glanray Corporation, Samuel J. Wolf, and their officers and agents as such, at Los Angeles, Calif., were engaged, according to a statement of the Postmaster General, in conducting a scheme or device for obtaining money through the mails by means of false and fraudulent pretenses, representations and promises. By the authority vested in him, the Postmaster General closed the mails on August 30 to the concerns.

The Glanray enterprise is operated as a California corporation and was chartered in June 1934 with a reported capitalization of \$25,000. The officers of the outfit consisted of S. J. Wolf, president, and Mrs. Sylvia B. Wolf, his wife, as vice president, secretary and treasurer. The business consists of promoting through the mails the sale of electrically heated prong-like devices called "Glanray" and "Prostal-Ray" for so called "prostate gland trouble."

Contact with prospective customers was made by means of advertisements inserted in publications having a national circulation. A specimen of the "come-on" bait is reproduced.

PROSTATE GLAND Brings Device Results

Stop night rising, leg back pains, nervousness, low vitality. Treat yourself at home. First cost is last. FREE BOOK. GLANRAY CORP., DEPT. F, LOS ANGELES, CALIF.

Other advertisements, as quoted by the Post Office fraud order, contained such implied promises and statements as:

"The Glanray automatically heats and massages the Prostate, helps nature to restore the gland to health! Naturally, when the prostate is back to normal all the aches and pains caused by its inactivity disappear. Why suffer the misery of Prostate trouble when Glanray is guaranteed to help you or your money is returned? Many doctors concede that heat massage is the proper treatment for prostate trouble."

The generic term "prostate trouble" is particularly objectionable, because it implies that all abnormal conditions of the prostate are the same and, therefore, respond to one line of therapy, namely, the Glanray and Prostal-Ray.

The victim of real or imaginary symptoms referable to the male perineum who succumbed to the "we want to help you overcome your aches and pains" ballyhoo received, on remittance of \$12 the Glanray apparatus, a hard rubber, prong-like device four inches long, with a bulbous end some three-quarters of an inch thick and with a circular shield for regulating the depth of rectal insertion. Attachments consisted of an electrical cord with switch and sockets and a ten watt red bulb for use as a gauge. A special lubricant, composed of 71 per cent aspirin in a petrolatum base, completed the equipment. If the prospective purchaser failed to warm to the \$12 gadget, the company had a "simplified electrical device," that is, it you have \$4.85 in cash.

The unhappy sufferer from any one of the innumerable conditions causing genito-urinary symptoms is led to believe from advertisements of the Glanray type that frequency of urination means only one condition—"prostatic trouble." The fact that frequency of urination is only a symptom of bladder irritation, which may be brought about by an encyclopedic list of conditions, either of psychogenic or organic origin is of course brought to the attention of the prospective Glanray purchaser. Especially unwarranted in the Glanray copy was the fear appeal.

Are you face to face with an operation for Prostate Gland? Is the surgeon just around the corner? If you have the Prostal-Ray, you will not make you as good as ever? Operations do not always cure. Ask any doctor if he will guarantee it. Glanray offers a knifeless drugless simple safe home treatment for Prostate Gland.

trouble. The entire cost of Glanray is only a mere fraction of the cost of a surgical operation. We are convinced that you can give yourself a better massage with Glanray than a doctor can give you.

The bewildered patient who succumbed to the Glanray copy, "Danger Signals for Men," was not told by the callous promoter that stone in the bladder, carcinoma of the prostate, carcinoma of the bladder wall, tuberculosis of the bladder, ureter or prostate, contraction of the bladder neck stricture of the urethra, nerve degeneration associated with cerebro-spinal syphilis, were but a few of the pathologic conditions that may cause so-called "bladder weakness mental despondency, leg, foot and back pains, night rising irritability" for which the Glanray device would be worthless.

The suggestion in the advertising that using the Glanray or Prostal Ray devices would enable one to "avoid doctors' bills" would be dangerous advice to a person in the pre-cancer stage. The victim could as reasonably hope to "avoid doctors' bills" by postponing the period for radium, x-ray or surgery until too late.

Particularly untruthful was the statement "There is no biological reason why a man should not maintain his mental and physical vigor to the ripe old age of seventy years or even more," it being implied that the device exploited by Wolf would "restore you to your old-time vigorous manhood."

For all the Prostal-Ray and Glanray blatant advertising copy, no witness, either expert or lay testified on behalf of the respondents at the hearing, according to the Post Office Solicitor's report of the case.

The exploitation by periodical advertisements of such devices as the Glanray and Prostal-Ray is another example of the heartlessness of the commercially-minded. The postal authorities are to be commended for closing the United States mails to such devices as the Glanray and Prostal Ray.

Correspondence

SERUM TREATMENT OF POLIOMYELITIS

To the Editor—We have read the editorial on the serum treatment in poliomyelitis in the issue of THE JOURNAL OF THE AMERICAN MEDICAL ASSOCIATION of August 8 with a great deal of interest. With certain of the points made in the editorial we are inclined to take issue.

In the first place, reference is made to "the almost universal observation of rapid symptomatic response with a drop in temperature and improvement in symptoms even with the small doses of serum in vogue at that time." We have never been impressed with this. We have seen quite as marked improvement in symptoms following a lumbar puncture. Indeed, we have not infrequently observed an exacerbation of symptoms after serum was given intraspinally.

Attention may be called to a typographical error in the paragraph referring to Dr. Park's statement. The fatality rate in the untreated cases was 0.9 per cent, not 9 per cent.

The editorial quotes from the report by the New York Academy of Medicine: "The untreated group was indeed a much milder group than the treated group. The results of the study are therefore inconclusive." To the inferences implied by this statement, we take most decided exception. When a patient is seen in the preparalytic stage, no prognosis can be made with regard to the ultimate severity of the case. Patients with a meningeal type who recover with no evidence of paralysis often appear severely ill at the onset. On the other hand, not infrequently patients with a mild onset develop severe paralysis as the disease progresses. To quote from Kramer, Aycock et al., "In a disease so unpredictable as poliomyelitis, where there is no single symptom or physical finding in the preparalytic stage to indicate the outcome, nothing short of an experiment with alternate series of cases would serve to establish the efficacy of convalescent serum." We are therefore unable to understand on what ground the workers

in the Academy of Medicine group could have decided that the untreated cases were milder.

If we understand the conclusions of Kramer and Aycock correctly, their unwillingness to draw conclusions as to the efficacy of the serum was based on the relatively small number of patients studied by them. It seems to us that this objection has been overcome when the total number of cases reported in the study of 1931 is considered. This series comprised in all a total of more than 1,100 cases, nearly equally divided, and observed by three different groups of workers, namely, the Health Department of New York City, the Academy of Medicine and Kramer and Aycock. It seems to us that this number of cases is sufficiently large to warrant the drawing of a quite definite conclusion that the convalescent serum is of no value in the treatment of poliomyelitis.

It is to be noted that in the three recent favorable reports cited in the editorial by Jensen, Cowie and Levinson, there were no controls. This leaves their work in the same questionable position as the favorable reports published before 1931.

As regards the method of administration and the dosage, attention must be called to the fact that the reports have been equally favorable regardless of these two factors. For instance, in the eastern part of the United States and in Australia, large doses intraspinally and intravenously were used, in California large doses intramuscularly, in Canada, small doses—from 20 to 25 cc—intramuscularly. The results were always favorable.

Certainly, in view of these facts, those who are still unconvinced and who wish to continue the use of the serum should use it in alternate cases, and draw conclusions only from fairly large series.

GARLIC ODOR TO BREATH

To the Editor—Since you have published correspondence from Dr. Haggard (THE JOURNAL, September 12, p. 895) in which he criticizes the work of C. E. Richards and myself (THE JOURNAL, August 8, p. 409) in such a way as to leave the question of garlic breath odor in doubt, I wish you would publish this additional correspondence.

We have reread Dr. Haggard's report (THE JOURNAL, June 15, 1935, p. 2160) and his quotations from his work, and we believe that the conclusion at which he arrived from his experiments should be the same as he published, namely, that onion or garlic breath odors "arise solely from particles of onion or garlic retained in the structure about the mouth." If we appeared to be "anxious to throw discredit" on his work it must be because of our understanding of the word "solely" as he used it. We disagree about his use of that word and we also disagree about his use of the word "wholly" in his recent correspondence. He ascribed to us a belief that breath odor comes wholly from the lungs. We made no such sweeping conclusion and we implied nothing more than was shown in our experiments, namely, that garlic breath odors do come from the lungs and that in the subjects used in our experiments these odors came only from the lungs. This we proved and Dr. Haggard, in his recent correspondence, conceded it in regard to garlic oil. Whether or not that concession is consistent with Dr. Haggard's use of the word "solely," I cannot tell from his writings. We have no doubt that when particles of garlic or onion are retained in the mouth, they give forth an odor.

Dr. Haggard criticized us for relying on the sense of smell rather than on chemical methods such as he used. Since the discussion concerns itself with garlic and onion odors, it would seem that the actual detection of these characteristic odors by the sense of smell is preferable to Dr. Haggard's chemical tests, which he admits are nonspecific. In his paper he not only admits that garlic odors are easily detectable at as low a

theoretical concentration of the oil in the breath as 0.00015 mg per liter (the lowest recorded by him) but further advocates our method by making his "crucial" experiment by the detection of odor alone. In his recent correspondence, Dr Haggard did not defend his chemical methods. On the contrary, he suggested that we do more experiments by the smell method. This, I take, is a concession that our experiments were not fundamentally bad because of the smell technique.

There remains, then, but one important point—that is, to convince Dr Haggard and your readers that our feeding experiments were done with garlic and onion in amounts, as he says, "within reason" (quantity not stated). Let us, then, give this additional information. The food (soup and salads) was prepared by hospital dietitians in hospital kitchens, with one exception. In experiment 2 the subject with complete tracheal fistula went to a restaurant and ate "mixed vegetable salad including Bermunda onion and garlic." This salad was prepared by the proprietor. The subject came thence to our laboratory and said he relished his food—meanwhile blowing off garlic fumes from his tracheal fistula. This we feel is an amount "within reason" and so concludes the matter. We believe, as does Dr Haggard, that when facts are clearly stated the matters of discredit and interpretation take care of themselves.

M A BLANKENHORN, M D, Cincinnati

INQUIRY ON THE "SAFE PERIOD," BY THE NATIONAL COMMITTEE ON MATERNAL HEALTH

To the Editor—In line with our interest in "medical aspects of human fertility," we are impressed by the extensive and increasing interest in and reliance upon the so-called "safe period" as a means of contraception. There is urgent need for determining, as accurately as possible, whether there exists, for the regularly menstruating woman, a predictable and reliable moiety of her cycle in which fertilization is impossible. The National Committee on Maternal Health is undertaking to collect pertinent data which, by reason of their source, will be of exceptional value.

We seek to enlist specially qualified married couples who will scrupulously keep and transmit to us—confidentially, of course—accurate and complete records of menstruation and coitus over a long period of time, several years if possible. We suggest, though not exclusively, couples of whom one or both are, say, physicians or graduate students or faculty members or research workers in biologic or other scientific departments, therefore competent to furnish trustworthy records and also scientifically interested in contributing to this investigation.

A couple such as we wish to enlist would prefer not to have a pregnancy develop during the next year or more, although if one did develop it would not be calamitous. Accordingly, the couple would observe the so-called "safe periods" as their sole means of avoiding conception. If that succeeds, and then the time comes when they desire a child, they would reverse their practice confining coitus to occasions outside the "safe period," or they would at least restrict intercourse to the moieties of the menstrual cycle when, theoretically, pregnancy is most likely to result, and then record how soon it does result. Needless to say, there must be no known or probable factor of involuntary sterility in either one of the couple.

The frankly experimental character of the coital practices on which these records are based and the special qualifications of the recorders, will make these data uniquely valuable.

The committee is peculiarly fitted to collect these records. Its territory is large enough to encompass couples in number adequate for the investigation—couples who, by reason of their particular qualifications and their willingness to volunteer, must be few in any one community, no matter how large the latter may be.

On application, we shall distribute to individuals simple records and brief instructions easy to follow. We hope to reach from as many as possible who are reached, directly or indirectly by this announcement. Please address National Committee on Maternal Health, Inc., New York Academy of Medicine Building, 2 East 103d Street New York, N Y

RAYMOND SQUIER, M D, New York
Executive Secretary, National Committee
on Maternal Health

Queries and Minor Notes

THE ANSWERS HERE PUBLISHED HAVE BEEN PREPARED BY COMPETENT AUTHORITIES. THEY DO NOT, HOWEVER, REPRESENT THE OPINIONS OF ANY OFFICIAL BODIES UNLESS SPECIFICALLY STATED IN THE REPLY. ANONYMOUS COMMUNICATIONS AND QUERIES ON POSTAL CARDS WILL NOT BE NOTICED. EVERY LETTER MUST CONTAIN THE WRITER'S NAME AND ADDRESS BUT THESE WILL BE OMITTED ON REQUEST.

TOXIC NEPHRITIS FOLLOWING USE OF PICRIC ACID NASAL SPRAY

To the Editor—Could the following cases be due to the picric acid alum spray described by Dr Charles Armstrong or just coincident? Case 1. A white boy, aged 12 one of seventeen living children, died whose only illness since infancy was influenza about four years ago and a light case on September 7 when perfectly well was given a 1-2-3 of picric acid alum solution. He became nauseated but did not vomit. September 9 his mother noticed a slight swelling of the face and after the second spray on that day there was considerable nausea and by afternoon a generalized edema. September 10 there was difficulty in voiding, vertigo and marked fatigue. I saw him in the office on the morning of the tenth. The temperature was 100 pulse 108 respirations 28. Anasarca was present. The throat was slightly red. There were a few minor rales in both bases. The urine voided in the office had a smoky albumin color, albumin was three plus. It contained many red blood cells and many casts mostly granular. September 12 the urine was much improved and the edema was less marked. Case 2. A Negro boy aged 10 the second of six living children none dead was doctor treated for worms when 2 years old, and had never been sick since. September 7 he was sprayed and developed an intense pain in the epigastrium but did not vomit. On the 8th he felt fairly well but after spraying on the 9th the pain in the abdomen was much worse with nausea but no vomiting. September 11 he was too sick to go back for spraying and anasarca was present. When I saw him September 17 there was a temperature of 101 with pulse 92. There was generalized edema. The throat and the heart were normal. There were a few moist rales in both bases. The urine voided in the office was about the same as in case 1. September 20 he had convulsions lasting about one and one-half hours. September 21 there was slight improvement with the urine showing less albumin, fewer red blood cells and not so many casts. Blood slides on both of these children were normal. There were no sores and nothing was present in the history except the spray that could to my mind account for the nephritis.

L J RUTLEDGE MD McComb Miss

ANSWER.—The two cases described should certainly be considered examples of toxic nephritis induced by the picric acid alum spray. The toxicity of picric acid or trinitrophenol has been subjected to experimental and clinical study since 1827. Internal administration for febrile conditions was attempted by Braconnet in 1830 but soon was shown to be too dangerous. The chief risk of picric acid poisoning has been in industry and particularly in munition manufacture. During the war the French found trinitrophenol but slightly less toxic than dinitrophenol. The grave dangers of internal administration of dinitrophenol need no further emphasis here.

The systemic effects of trinitrophenol are gastro-enteric, hemorrhagic nephritis and acute hepatitis with hemolysis of the erythroplasts. Extensive absorption may cause yellow discoloration due to picric acid staining but the acute hepatitis also causes a true icterus. These two children thus presented quite classic evidences of picric acid poisoning. In the second case the recurrence of symptoms promptly following a second spraying with picric acid-alum solution is particularly convincing of the etiologic association. The transient nature of the nephritis, which appeared to tend toward healing speaks for a temporary poisoning rather than infection as the causative agent.

It is well known that the introduction of nitro groups into phenol compounds greatly increases their toxicity (Hamm, Alice Industrial Poisons in the United States New York: Macmillan Company 1925). The susceptibility to renal damage

nitrite poisoning is much greater in children than in adults, instances of nitrite intoxication with methemoglobin formation are not unusual in small children from even small doses of nitrite-forming drugs. The greater vulnerability of children to nitrites may be a factor in making the nitrophenols, such as picric acid, relatively much more toxic to children than to adults. At least the probability of such additional danger suffices to warrant expressing an emphatic warning as to the dangers of possible picric acid absorption. Certainly it is not justified to advocate a method of prophylaxis of somewhat uncertain efficacy against a possible danger when such probable risk is involved.

INTRACULAR PAIN

To the Editor—A man aged 29 developed bilateral intra-ocular pain at the age of 17, which has persisted constantly to the present. It is quite comparable to a toothache in nature and does not radiate. The intra-ocular pressure is normal and the patient has worn glasses since the age of 15 for simple myopia. There seems to be acute exacerbations at times in which the pain increases in severity and in addition there is mental depression with loss of ambition. The patient I might add is quite intelligent and a college graduate. The acute attacks remit after a few weeks and recur within five or six months. From general appearances one would not suspect that there is any complaint. Competent neurologists ophthalmologists otolaryngologists and internists have not been able to find a pathologic basis for this complaint. The sphenopalatine ganglion and nasal mucosa have been cocaineized with no effect. Most men have considered this a psychoneurosis and psychoanalysis has been advised but the patient does not feel that such an expense would be justified. Please omit name. M D Connecticut.

ANSWER—The sources of intra-ocular pain in the absence of manifest inflammation are so varied that it is extremely difficult to answer this question. One of the most prolific sources of such pain is an anomaly of the muscular apparatus of the eye. Such a condition can be discovered on competent ophthalmic examination and corrected without great difficulty. Another not infrequent source of intra-ocular pain is a low grade chronic inflammation of the posterior paranasal sinuses. This may be somewhat difficult to diagnose and may require repeated examinations of the sinuses with radiopaque material.

RECURRENT FEVER IN CHILD

To the Editor—I have recently seen a girl aged 14 with a history of recurrent attacks of fever since childhood. When she was 3 years of age she had the first recognized attack, which lasted about three weeks. Her mother states that there was no complaint or objective symptoms except weakness and fever. Since that time she has had attacks varying from weekly intervals to biyearly intervals and varying little from the first attack, except that recently the attacks have been of shorter duration. She has had measles, mumps and chickenpox. There is no record of rheumatic fever or scarlet fever. She had pneumonia (lobar) and was treated with antipneumococcal serum which shortened the disease very much. This occurred in 1933. I saw her first in October 1935 when the temperature range on five successive days at maximum was 99 100 101.5 102 and 99 F. Thorough physical examination gave no lead and because of the history of weakness I did a Mantoux test which was entirely negative. Her appetite remained good throughout the fever period, and two days after a normal was reached she was up and returned to school. March 4 1936 she began to have fever again and on six successive days it was 99 99.5 102 100 99.8 and 99. The pulse is usually between 80 and 90 with fever. Her hemoglobin is 84 per cent red blood cells 4 300 000 and leukocyte count 7 600 with a normal differential. The urine is normal. She has been carefully observed and taken to specialists but no definite diagnosis has ever been made. I have kept tuberculosis in mind and have thought of various other conditions such as undulant fever intestinal parasites and even endocrine disturbances but I cannot find evidence to support any definite diagnosis. Could you suggest any diagnostic possibility? Please omit name.

M D New York.

ANSWER—It is obviously difficult to determine the precise cause of the obscure fever from which the patient mentioned is suffering. The causes for these obscure fevers are numerous and one should repeat some of the examinations already made. It would be well to ascertain the condition of the child's tonsils to determine if they were the site of chronic infection. One should also note whether or not there is enlargement of the cervical or other lymph nodes.

An x-ray examination of the thorax should be made to visualize the condition of the lungs and the bronchial and mediastinal glands, as well as the size and shape of the heart. Pulmonary tuberculosis may be detected by the presence of a primary lesion in the lung or by enlargement of the bronchial lymph nodes. The tuberculin skin test should be repeated and, for the purpose of completeness, a Wassermann test should also be made. An agglutination test for undulant fever should be employed. Morning specimens of urine should be obtained at frequent intervals and examined chemically and particularly microscopically for pus cells. If a sterile specimen of urine can be obtained, it should be examined for micro organisms. If

there is any suspicion of kidney involvement, intravenous or oral urography, as suggested by Swick, may be tried in order to visualize the kidney by means of a pyelogram. The abdomen also should be investigated, particularly the size and position of the liver and spleen, and the region of the appendix should be examined for tenderness and rigidity. The fecal evacuations should be examined for the presence of pus, mucus, occult blood, parasites and their eggs, as well as for amebas, and bacteriologic studies of the stool may also be carried out. It must not be forgotten that in some patients all these tests may be negative and the child may present variations in temperature owing to an unstable heat regulating mechanism. Sometimes emotional excitement, fright and fear, as well as excessive muscular exercise may cause temperature elevations of varying degree.

ALKALINIZATION IN ULCER THERAPY—IODIDES IN TUBERCULOSIS

To the Editor—Recently I saw a patient who while suffering from a gastric ulcer took over a long period of time large quantities of mixed alkalis including sodium bicarbonate. He then developed uremia, having marked clinical symptoms and a blood nonprotein nitrogen of 111, urea nitrogen 65 creatinine 3.7. The specific gravity of the urine was fixed at 1.010 and there was a trace of albumin, the reaction being alkaline. The blood pressure was never above 160/80 and during the stage of coma fell to 100/40. The patient has made a remarkable recovery now having a normal blood nonprotein nitrogen the urine is free from albumin and the specific gravity has reached 1.018. The question is Did the alkalosis have anything to do with the production of uremia? If so will you please explain the manner in which it acted? Is permanent damage likely to have resulted? The prevailing opinion seems to be that potassium iodide is detrimental to a tuberculous person. Is this due to the potassium or the iodine? If due to the iodine, do all the iodides have a detrimental effect when given in moderate doses. Please do not mention my name or town. M D, Oklahoma.

ANSWER—One of the objections to the method of treatment of peptic ulcer by accurate neutralization of the hydrochloric acid is the fact that alkalosis may occur. This is manifested by an elevation of the blood carbonates and symptoms of renal irritation. It has been shown by many observers that not alone renal disease but any lesion of the genito-urinary tract may be aggravated by excessive alkali therapy. Fortunately most of these conditions are transitory and improve with cessation of alkali therapy. Occasionally it may be necessary to administer some form of acid medication, as ammonium chloride or even hydrochloric acid, to overcome what seems to be a disturbance in the composition of the colloids of the cells.

Iodides in any form are contraindicated in patients with pulmonary tuberculosis.

CLIMATIC CARE OF INFECTIOUS ARTHRITIS—ARTHRITIS AND PREGNANCY

To the Editor—I am anxious to determine whether or not there are any places in the world relatively free from infectious arthritis. In attempting to look this matter up I find that the literature is vague. My wife has a relatively mild bronchiectasis in the right lower lobe of about ten years' duration. On postural drainage about a tablespoonful of sputum is raised daily with no blood. A year ago she first developed an infectious arthritis in the fingers of the right hand and right wrist. The pain and swelling subsided during the spring and summer. During the past month the condition has recurred in the wrists and right index finger. She is about six months pregnant. What effect, if any does mechoyl have on pregnancy? Could you advise me as to whether or not climatic conditions in any part of the world would offer enough to be considered in making our future locations? Do you have any therapy to suggest? Please withhold name.

M D, Indiana.

ANSWER—The incidence of arthritis occurring among the natives of areas in which the climatic conditions are usually warm and dry and there is an abundance of sunshine has been shown to be lower than in sections of the globe where there is greater humidity and less sunlight. The migration of individuals suffering from arthritis to the dry, warm areas increases the census of such patients in these localities. Also patients suffering from bronchiectasis are benefited by climates in which the humidity is low. A connection between a mild bronchiectasis and symptoms of arthritis has been postulated but not definitely established. In this country the climate of Arizona and New Mexico seems to offer the best advantages for these patients. Unfortunately, in most cases, residence in such climates affords relief only while the patients are there, and return to a climate in which there is colder weather, greater humidity and less sunshine frequently leads to a relapse and an exacerbation of all of the symptoms.

There is no evidence that mechoyl (acetyl-beta-methylcholine chloride) has any deleterious effect on pregnancy, but the various physiologic effects of this drug are still being studied.

Pregnancy in itself adds a strain on the calcium and phosphorus stores of the body. Within recent months there has

been increasing evidence that calcium and phosphorus deficiencies may in some instances predispose to the development of arthritis. It is possible that the onset of this last attack of arthritis when the patient was five months pregnant has a significant connection. Both because of the pregnancy and of the arthritis, one would seem justified in recommending a rather large intake of vitamin D and of calcium in the form of from 1.3 to 2 Gm of calcium lactate daily, in addition to a permanent change of residence to a more suitable climate.

REACTIVE CHEST APPLICATION

To the Editor—By what means do the reactive chest applications as mentioned in the article on therapy of coughs in *THE JOURNAL*, February 1 act? I can see how there might be a momentary reaction due to the temperature of 60 degrees. But how can any other reaction occur after the compress is on for more than a few moments as in the case of the ambulant patient who leaves it on all night? Surely the skin temperature is reached in a very short time. If a reaction is desired and beneficial why would it not be better to change the compress every ten or fifteen minutes in the care of the bed patient rather than in two or three hours? Earlier in the article the author states that chilling of any part of the skin more especially of the chest causes bronchitis patients to cough more. In my experience cold compresses to the upper part of the chest frequently work like a charm in stopping a cough in children with acute bronchitis when the cough is light. Textbooks and medical literature are at such a variance with regard to the use of warm and cold compresses in chest conditions that one wonders whether we are all wrong. Please omit name and address.

M D Minnesota

ANSWER—A reactive "chest application" consists of a well wrung-out cold compress covered with dry flannel so that the edges of the latter liberally overlap the moist fabric. It is usually applied at bedtime just before the patient enters his previously warmed bed. If the compress is properly employed, the momentary constriction of the blood vessels of the chest is followed by a hyperemia lasting for hours, and the compress should be dry by morning. It is then well to apply a reactive chest ablation," which is nothing more nor less than a dash or two of cold water applied to the chest followed by brisk rubbing and drying so as to leave the skin of the chest in a glow of hyperemia. It is not the vasoconstrictive action of the cold but the hyperemia reaction from it that is aimed at in this treatment. If the patient does not "react" by feeling warm and comfortable and if the compress feels cold and clammy and chills the patient for more than the very brief initial shock, it does harm and should be promptly discontinued.

INDUSTRIAL HAZARD OF SODIUM SULFATE DUST

To the Editor—For a number of years the so-called salt cake or crude sodium sulfate has been imported through Gulfport, Miss. For the past ten or twelve years I have done the major portion of the accident work on the shipping front. It is only within the last few months that any one has complained of experiencing any bad effect from the inhalation of salt cake dust and these complaints came during an epidemic of influenza among the strike breakers who were later let out. Since that time work on the water front has been limited and every now and then some one complains of suffering bad results from this cause especially when he knows that shipping will be scarce for a few weeks. Will you kindly advise me if there are any statistics showing that a few hours work at a time inhaling this dust will have a damaging effect on the human lung? One man claims to have developed tuberculosis as a result of exposure. As this material contains some sulfuric acid unless too strong I would rather think it a pulmonary antiseptic rather than an irritant. Kindly give me your opinion at your earliest convenience. Please omit name.

M D Mississippi

ANSWER—Sodium Sulfate (Na_2SO_4) is well known to medicine in the form of Glauber's salt ($\text{Na}_2\text{SO}_4 \cdot 10\text{H}_2\text{O}$), which is the hydrated sodium sulfate. Large doses, such as 30 Gm, are frequently administered, which fact at once marks this substance as essentially free from toxicity. In various portions of the United States and in other portions of the world, sodium sulfate is mined as such. No events have taken place indicating toxic properties arising from the inhalation of sodium sulfate dust. In addition to the natural product sodium sulfate may be manufactured. In the Leblanc process of manufacturing soda sodium sulfate is first made by treating common salt with sulfuric acid. This yields "niter cake," sodium acid sulfate (NaHSO_4). Later this niter cake is changed over to the "salt cake" through further contact with brine.

In the manipulation of both the natural and the manufactured product opportunity for exposure to dust is provided. At no time have any injuries been noted from the action of this salt. In the manufacture of sodium sulfate opportunities for possible harm arise from exposure to the fumes of sulfuric and hydrochloric acid in connection with furnace operations. In some manufacturing processes leading to sodium sulfate sulfur

dioxide may arise and occasionally hydrogen sulfide is produced. However, it is emphasized that these exposures are not to sodium sulfate itself but to intermediate chemicals and by-products incidental to its manufacture.

It is conceivable that some sulfuric acid might be present in uncombined form along with the sodium sulfate, but if so this would serve chiefly as a minor irritant to the skin and to the mucous membranes. In general it may be believed that sodium sulfate is one of the most innocent of industrially used chemicals. The repeated reference in the query to labor difficulties, strikes and shortage of work probably stands in relation to claims for damages associated with this salt as the cause. It is high time that the public should realize that not all dusts are harmful. The chances that sodium sulfate may have been responsible for any substantial injuries under the circumstances described are remote.

FETUS PAPYRACEUS

To the Editor—A mother has been anemic and edematous with a heart lesion. A full term girl was born who was perfect in every respect. Within the sac of fluid there was a 4 months old fetus flattened by pressure from the full term child. There was a small placenta within the sac leading to the fetus. Delivery was made after three hours of labor with rather profuse hemorrhage. The condition today is good.

M.D. Ohio.

ANSWER—The case described is unusual and occurs generally in twin pregnancies but also may be found in cases of triplet gestations. In the case cited, the patient's anemia and heart condition most likely had no etiologic significance. The condition is usually associated with dichorionic or double ovum twins when one fetus dies during the early months of gestation. Instead of being expelled it remains in the uterus, where it and its placenta are compressed against the uterine wall by the normally growing child. The liquor amni of this sac is absorbed or expelled. The dead, flattened fetus is called fetus papyraceus or fetus compressus. Occasionally such a fetus is unknowingly left behind in the uterus after delivery of the live child and if this occurs it may give rise to puerperal infection. The placenta of a fetus papyraceus is small, hard and pale and may be separate from or contiguous with the placenta of the normal child.

SEBORRHEIC DERMATITIS

To the Editor—I have a patient who has an oily crusted dermatitis of the skin of her neck and face. She has been treated by a skin specialist who made the diagnosis of seborrhea due to dandruff sensitivity. She has not responded to various sulfur preparations that he has prescribed and the dermatitis continues to return after short remissions. Please advise treatment. Could an extract of the dandruff be made to desensitize the patient? Please omit name.

M D North Carolina

ANSWER—In a person with seborrheic dermatitis there is apt to develop a superimposed dermatitis from exposure to cutaneous irritants. Frequently it is found that what is thought to be a recurrence of seborrheic dermatitis is in fact rather a flare up of irritant dermatitis on a seborrheic habitus. It is usually due to the action of an irritant to which the person is sensitive. In a woman with a dermatitis confined to the face and neck, the cause should be sought in materials to which she is exposed such as toilet articles or fur collars. Frequently a good history brought out by pointed questioning will suffice to identify the exciting agent. If not, recourse must be had to patch tests done in a routine manner with the substances that are in contact with her face.

Uncomplicated seborrheic dermatitis usually yields readily to topical treatment, although there is some tendency to recurrence. It is generally thought that impaired health with constipation and other gastro-intestinal disturbances, anemia, and other conditions predispose to seborrheic dermatitis but the experience is that it is seen constantly in persons with normal health. Recently there has been some evidence from one source to indicate that *Pityrosporon ovale* may be the etiologic agent.

It is well to have patients with seborrheic dermatitis avoid the things that are likely to flush the face—alcoholic liquors, hot and spicy foods or hot towels to the face. For all practical purposes topical applications with sulfur seem to be the most useful alone or combined with salicylic acid. Suitable formulas are given in all textbooks of dermatology. Sometimes a few exposures to x-rays are necessary and ordinarily with this regimen the dermatitis can be readily got rid of. Treatment with an extract made of the dandruff scales is not commonly practiced, and there has not been sufficient experience on which to evaluate it.

AMENORRHEA, DYSMENORRHEA AND CERVICAL
STENOSIS

To the Editor—Mrs M aged 23 first came to me two years ago complaining of amenorrhea and severe dysmenorrhea dating from six months previously. She began menstruating at the age of 16 was always regular and had a moderate flow lasting from four to five days. Her past history was otherwise negative. The patient was thin had small bones was 5 feet 5 inches (165 cm) tall and weighed 102 pounds (46 Kg). Aside from the underweight no other abnormalities were noted until examination of the genital tract. This showed a third degree retrodisplacement of the uterus with a pinhole external os. There was no cervical or vaginal discharge and no erosion of the cervix. The uterus was freely movable and not tender. There was no tenderness nor were masses palpable in either fornix. In view of this and after pessaries had failed in the treatment of the displacement an operation at which a suspension of the uterus and dilation of the cervix would be done was advised and performed. No curettage was thought best by the surgeon. A glass rod was left in the cervical canal but the pain was so severe that it had to be removed on the fourth day. This procedure gave some slight relief from the dysmenorrhea for the next three periods but had no effect on the amenorrhea. Since her trouble had its onset at about the time she had become engaged to be married one physician felt that there might be some sexual background to her difficulties and therefore advised her to be married. This was also done but with no effect. Since that time I have given her gland products intramuscularly as follows for the first ten days following her period 1 cc of theelin on alternate days. For the remainder of the intermenstrual period 1 cc of antuitrin S. This resulted in no improvement. During the next intermenstrual period she received beginning two weeks before the next period was due 0.5 cc of follutein plus 3 cc of anterior pituitary (Squibb) on alternate days. No improvement was noted. The only drug that gives her any relief from the dysmenorrhea with the exception of narcotics which I have refrained from giving is oral sodium. She has been slightly anemic at times but has always responded to treatment for this. I have not succeeded in getting her to gain any weight. I have thought that she might become pregnant and that this might solve the difficulty but she has not. Any advice you may give me with regard to this case will be greatly appreciated. Please omit name and town.

M D Connecticut

ANSWER—The apparently paradoxical combination of amenorrhea and dysmenorrhea at once suggests stenosis of the cervix. Since the cervix has been dilated this possibility can be almost ruled out, but the possibility of a foreign body in the uterus has not been ruled out. Presumably the patient still has cyclic monthly pain but does not menstruate. She should have a basal metabolic rate determination, since low rates may be accompanied by amenorrhea, more rarely by dysmenorrhea. Even if the rate is not low, say plus 5, small doses of thyroid substance (from 0.03 to 0.065 Gm daily) are worth a trial. The combination of cervical stenosis, retroversion and acquired dysmenorrhea strongly suggests endometriosis. Endometrial implants observed when the uterus was suspended, or increasing nodules in the culdesac at present, would almost assure the diagnosis. Dysmenorrhea due to endometriosis will not be relieved by endocrine therapy unless amenorrhea is produced. Pituitary disorders, including Simmonds' disease, should be considered. If a diagnosis of definite organic or dysfunctional disease cannot be reached, the patient should be encouraged to become pregnant in hope that the ensuing dilatation will be beneficial. Sterility studies may be necessary. Hertzler believes that small doses of potassium iodide are almost specific for dysmenorrhea, atropine sulfate, from 0.4 to 0.6 mg, may be used two or three times a day just preceding the period.

PREPARATION OF POLLEN ANTIGENS

To the Editor—Please send me the detailed technic for the extraction of pollen foods and epidermals. What is the best extracting fluid to use? Approximately how long do these extracted fluids remain potent? Please give the detailed technic for extraction of house dust. What is the technic for dialysis? In the preparation of which materials is this method used? Please send me any references that will be of value to me. Kindly omit name.

M D Ohio

ANSWER—The details for extracting pollens, foods and epidermals are given in New and Nonofficial Remedies in the section on Allergic Protein Preparations. For pollen extracts the 5 per cent solution of dextrose, which is isotonic, is recommended. It must contain 0.5 per cent phenol as a preservative. For foods and epidermals, a solution containing 50 per cent glycerin and 50 per cent of a solution containing 5 Gm of sodium chloride and 27 Gm of sodium bicarbonate per liter is recommended for the extraction. Extracts containing 50 per cent should be diluted with the sodium chloride-sodium bicarbonate solution before injection. These dilutions probably retain their potency for about thirty days if kept in the refrigerator. The glycerin extracts and the pollen extracts prepared with 5 per cent dextrose solution appear to retain their potency for at least eighteen months.

House dust may be extracted with the glycerin in salt solution mixture, about 20 Gm of the material removed with the vacuum sweeper from the patient's home being used. The dust is macerated with 100 cc of the solution over night, and the liquid is pressed out with glass rods and filtered.

Neither the use of 50 per cent glycerin nor the use of 0.5 per cent phenol as a preservative will kill bacterial spores, and it is necessary that all allergenic extracts be sterilized by passing them through Berkefeld, Seitz or Pasteur-Chamberland filters. The filter and all equipment must be sterile and must be adequately protected against the bacteria of the air.

All solutions used for either skin testing or treatment must be of proved sterility when tested according to the method described on page 469 of the U S P XI.

Extracts of foods are freed from irritating dialyzable components by dialyzing against large quantities of distilled water, vegetable parchment or "Visking" sausage casings being used.

SIMULTANEOUS ADMINISTRATION OF ERYTHROL
TETRANITRATE AND POTASSIUM
THIOCYANATE

To the Editor—Is there any incompatibility involved in using erythrol tetranitrate and potassium thiocyanate simultaneously i. e. in the same patient? Is potassium thiocyanate injurious to a patient with chronic nephritis? Please omit name.

M D Massachusetts

ANSWER—There is no therapeutic incompatibility, but it would not be wise to administer the two simultaneously until after the optimal dose of each has been determined. It might then be well to see whether their administration alongside each other improves the result obtainable from either. The precautions required in the administration of thiocyanate are so well given by Barker (The Blood Cyanates in the Treatment of Hypertension, THE JOURNAL, March 7, p 762) that it is best to refer to this article. Nephritis is no contraindication to thiocyanate but an indication for especially guarded dosage.

TREATMENT OF IMPOTENCE

To the Editor—A man aged 60 in excellent health, has always had a normal sex life. There is no venereal history. One testicle has been atrophied since the time he had mumps in adolescence without effect on his sexual activity. About one year ago he began to lose the ability to attain an erection when attempting intercourse except on rare occasions. Whenever erection is attained intercourse is normal with orgasm and ejaculation neither hurried nor delayed. His libido is unquestionably decreased. A peculiar thing about his weakness is that the patient awakens almost every morning about 4 or 5 o'clock with a perfect erection which is maintained without effort for from twenty minutes to a half hour. If the opportunity offers intercourse is normal. He may often arise and go about his toilet without sexual ideas or thoughts and the erection persists for fifteen or twenty minutes when it slowly subsides. It appears to have no relation to a full bladder as the patient frequently will empty the bladder and return to bed and in an hour or so the erection will occur. Also when contemplating intercourse a full bladder is a distinct disadvantage and he is sometimes able to accomplish an erection after emptying the bladder. Is this a usual condition and is it related to age? Is the condition simply senile or is it psychic or emotional? What would you suggest in the care of this case? Of course I appreciate that this is not a life and death matter but it is distinctly annoying and as such merits a doctor's best efforts. Have the new testis hormones proved of any value and what may be expected of them in patients between the ages of 60 and 70? I refer to the crystal line principle isolated by the Swiss as well as such products as androsten. Has any work been done on testicular grafting by the method of Dr. Stone of Johns Hopkins in grafting thyroids and parathyroids by first acclimating the graft to the tissues of the recipient by growing them on the tissue juices serum and plasma of the recipient before transferring the gland to its new host? What results have been attained? Please omit name.

M D California

ANSWER—It is not unusual for a man past 60 to find that his sexual ability is getting weaker, although with proper treatment it should become normal for his age. Morning erections are a good sign and the opportunity should be utilized for sexual intercourse if possible. There is no advantage of holding back from intercourse when sexually excited on the theory of conserving the sexual power. Morning erections with or without a distended bladder are not uncommon in both normal and partially impotent persons. From the history it seems that there is a mild priapism present in connection with the partial impotence, a not unusual combination. These mild cases of priapism generally go on to recovery but the blood should be examined nevertheless for the possibility of a leukemia.

Testicular extracts have no effect in cases of impotence for the simple reason that while the testicle makes the hormone, it does not store it but sends it at once into the blood, so that a piece of testicle will have too minute a quantity of hormone

to be of any use. There have been a few good results observed after testicular transplantation, but the cases are few and the results as a rule only temporary. It certainly is not necessary to go through such a formidable operation in the present case, in which a certain amount of ability is undoubtedly present.

The condition in the present case is no doubt due to a weakened condition of the sexual muscles, and stimulation of these muscles is in order. For this purpose the use of the sinusoidal-faradic current of moderate rapidity and as strong as the patient can bear without any pain is most effective. One cable is connected with a rectal electrode and the other with a wet-sponge electrode applied to the perineum and the current is allowed to pass for about ten minutes. Treatments may be given every three or four days. An outdoor life with periods of vacations is distinctly beneficial.

LOCALIZED BONE ATROPHY

To the Editor—An Irish housemaid aged 21 was referred to me for roentgen irradiation of the left elbow because of pain swelling slight redness and limitation of motion of several weeks duration. There was no recent trauma. About six years ago while in Ireland she sustained an injury to her left knee and also probably the elbow. She was not disabled and recovered promptly as far as the elbow was concerned. During the next five years she thinks she hurt her left elbow on several occasions when her left knee gave way and she either fell or tried to keep from falling. Otherwise she has always been well up to her present trouble. Roentgen examination disclosed a marked irregularity in the contour of the external condyle of the humerus, numerous circular clearly defined areas of osteoporosis in the condyle which perforate the cortex and similar areas in the head of the radius and olecranon process. The joint space is narrowed. No periarticular soft tissue swelling and no osteo-sclerosis of bone are present. A biopsy by an eminent pathologist disclosed extensive necrosis (partial and complete) of rather compact bone which in places was being revascularized. The diagnosis was post-traumatic necrosis with porofication due to revascularization. A series of diathermy treatments was given and another film just taken shows the areas to be filling in with new bone. I should like to know your opinion as to etiology pathology and references to similar cases if any are on record. Please omit name. M D New York.

ANSWER—The patient apparently has localized bone atrophy, of traumatic origin, involving the elbow, and possibly traumatic arthritis. The injury to the knee six years ago, probably resulted in a loose or fractured semilunar cartilage, which would account for the knee giving way. The repeated injury to the elbow occurring in the course of the falls may account for the changes in the joints and for the osteoporosis. The irregularity of the external condyle is probably the result of an unrecognized fracture, which occurred at the time of the original injury. The roentgenologic and clinical observations substantiate the opinion that an atrophic condition is present. The following references may be of interest.

KRUEGER'S METHOD FOR BACTERIAL ANTIGENS

To the Editor—Please send me Dr. Krueger's method of preparing bacterial antigens. In this particular method Dr. Krueger explains how he preserves the antigen without the aid of heat chemicals or any biologic treatment. AUBREY L LEWIS M D San Angelo Texas

ANSWER—Krueger's method (Krueger A P A Method for the Preparation of Bacterial Antigens, *J Infect Dis* 53 237 [Sept-Oct] 1933) follows. Mass cultures of bacteria are grown in Blake flasks on appropriate mediums. The cells are harvested in buffered isotonic solutions and are washed five or six times. After the final centrifugation they are suspended in the buffered solution, and the cell count is determined by the centrifuge sediment method described in an earlier paper (*J General Physiol* 13 553 [May] 1930). The dense suspension is placed in the mechanical grinder (Krueger, A P *J*

Infect Dis 53 185 [Sept-Oct] 1933) and is subjected to the grinding treatment for a period of ten or twelve hours. The suspension is then filtered through a 4.5 or 5 per cent acetic collodion membrane (Krueger, A P, and Ritter, R C. *J Gen Physiol* 13 409 [March] 1930) and is tested for sterility. It has been found that under ordinary conditions ultrafilters are distinctly preferable to Chamberland or Berkefeld candles, since the latter adsorb a considerable fraction of the active antigenic substances from solution. The procedure involves no treatment with heat, nor is there any possibility of denaturation by the action of chemicals."

THROMBOPHLEBITIS WITH INDURATION

To the Editor—A man aged 40 has a small brownish area on the inner side of the ankle just above the malleolus. This is slightly indurated at times underneath and again at times almost goes away. He states that there is no pain about it, but sometimes the induration extends through an area about the size of a silver dollar (38 mm). The skin over this area is slightly brownish but is not scaly. There is no sign of ulceration. Ten years ago the patient had a phlebitis in this leg and states that at times the leg has been slightly swollen since then and again there will be no swelling to amount to anything for months. The patient has no other trouble of any kind. What treatment would you advise for this? I presume there are some deep veins about this center but there are no varicose veins in this leg—at least none of any consequence. W

ANSWER—The condition described is a thrombophlebitic induration with a "resting" infection that occasionally becomes activated. All possible foci of infection should be searched for and eliminated. Teeth, tonsils and prostate are most important. Syphilitic etiology should be excluded. If the phlebitis followed an operation, the source of infection may be in infected pelvic veins. Small doses of x-rays not exceeding 100 roentgens with deep filtration are often helpful in softening the indurated area and clearing up the residual infection. Elastic support in the form of a zinc-gelatin boot or elastic adhesive tape reduces the swelling and also helps to soften the induration. Such indurated areas tend to break down with advancing age and form the base of intractable ulcers.

PSEUDOCOLLOID OF THE LIPS

To the Editor—I have a patient with a condition of the lips which appears to be Fordyce's disease (pseudocolloid of the lips). I have been unable to find anything definite for the treatment of this condition and would appreciate any information you can give me with regard to the etiology treatment and prognosis. Would radium or x-rays be of any value here? Please omit name. M D Minnesota

ANSWER—The lesions in pseudocolloid of the lips are most probably due to the presence of aberrant sebaceous glands in the buccal mucosa. The condition is a harmless one. The discovery is usually accidental and the condition, as a rule, does not give rise to any discomfort or symptoms.

The lesions may be destroyed with the cautery point, or x-rays or radium may be used cautiously to secure involution. Freezing of the parts with carbon dioxide snow is also of value.

MYDRIATIC FOR EYEGROUND EXAMINATIONS

To the Editor—What single mydriatic preparation is most practical for eyeground examination in the office? What is the best after-care to give these patients especially those who insist on driving their automobiles from the office? Please omit name. M D Wisconsin

ANSWER—Probably the most satisfactory single mydriatic for eyeground examination in which the paralysis of accommodation does not enter is 2 per cent eucatropine (euphthalmine). Two instillations at five minute intervals will produce adequate dilatation of the pupil in about fifteen minutes. If accommodation is not interfered with the eye under euphthalmine does not suffer any noticeable deterioration of vision. But, as a preventive against possible attacks of hypertension it is well to instill two drops of 2 per cent pilocarpine at five minute intervals into the eye before the patient leaves the office.

HYPOSPADIAS AND STERILITY

To the Editor—To what extent is a hypospadias with the opening at the base of the glans considered an impediment to impregnation? In a case in question there have been no other abnormalities found in husband or wife that would account for their failure to have children in twenty years of married life and it does not seem to me that the condition mentioned would be of much hindrance to the proper depositing of sperm. If published please omit name. M D Kentucky

ANSWER—Hypospadias of the first degree is rarely, if ever an impediment to impregnation.

LENGTH OF USE OF ARTIFICIAL EYE

To the Editor—I have a request from an attorney representing an insurance company as to the average usefulness of an artificial eye. In my own experience this is a very variable matter and depends principally on the care given the eye and the sensitivity of the individual to roughness and the matter of appearance and so on. I have never run across any reference to this in ophthalmic literature and would be very grateful if you can help me answer this question.

GEORGE N. HOSFORD, M.D., San Francisco

ANSWER.—The average life of an artificial eye depends on many conditions. Of course, the care to which the owner subjects the eye when it is not being worn plays a part, but in addition to that there are secretions from the eye which vary greatly in character. In some individuals these secretions attack the prosthesis so that the eye becomes roughened and even eroded in from six to twelve months. In other individuals that effect is entirely lacking.

A rather exhaustive treatise on artificial eyes may be found in the American Encyclopedia of Ophthalmology, volume I, page 621.

MANDELIC ACID IN PYELITIS

To the Editor—Recently I saw an article by Dr. Helmholz of Rochester, Minn., giving a new drug for the treatment of pyelitis. The article has been mislaid. Can you give me the information as to the drug or where I can find the reprint?

GEORGE J. ASTE, M.D., Chicago

ANSWER.—The new drug used in the treatment of pyelitis is mandelic acid, which can be used in the form of the ammonium salt in the dose of 3 Gm. four times a day. If the sodium salt is used, it is given in the same dose with 1 Gm. of ammonium nitrate or ammonium chloride four times a day to acidify the urine. The pH of the urine must be below 5.5 and the concentration of the acid about 0.5 per cent. This dose is for adults.

References

- Helmholz, H. F. Successful Treatment by Means of Mandelic Acid of a Child with Urinary Stasis and Infection. *Proc. Staff Meet. Mayo Clin.* 2: 231-232 (April 8) 1936.
- Helmholz, H. F. and Osterberg, A. E. The Rate of Excretion and Bactericidal Power of Mandelic Acid in the Urine. *Proc. Staff Meet. Mayo Clin.* 2: 373-377 (June 10) 1936.

RECIPE BOOK OF AMERICAN PHARMACEUTICAL ASSOCIATION

To the Editor—In Fantus's book, "The Technic of Medication," reference is made to a recipe book. Will you please tell me what that book is about, where obtainable, and its price?

CHARLES S. RAND, M.D., Jamaica, N.Y.

ANSWER.—The Recipe Book is published by the American Pharmaceutical Association and is obtainable from sellers of medical books.

A completely revised edition is now available. The price of this publication is \$5.

TECHNIC OF OPHTHALMIC SURGICAL PROCEDURES

To the Editor—Please send detailed information concerning the use of the Peters modification of the Bishop tendon tucker. Also intracapsular cataract extraction with the use of the Kalt capsule forceps.

CHARLES K. MILLS, M.D., McAlester, Okla.

ANSWER.—Detailed instructions as to the use of these two instruments do not belong in this column. Probably the best description of the use of the tendon tucker is by Peters himself and can be found in the second edition of "Extra-Ocular Muscles," by Luther C. Peters, 1936, page 303. For the use of the Kalt forceps the reader is referred to "Annales d'oculistique," 162: 489, 1925, or to "Die intra kapsulare Starextraction of Elsching" of 1932, page 45, or to "Surgery of the Eye" by Torok and Grout, 1925, page 282.

ANTHELMINTICS AS PROVOCATIVE FOR DIAGNOSIS

To the Editor—Is there any advantage to be derived from the administration of a provocative dose of an anthelmintic in an effort to diagnose intestinal parasitic infestation? Please omit name.

M.D., Indiana

ANSWER.—Provocative therapy is justified if a prompt diagnosis of worm infestation is demanded so that the time of waiting for the spontaneous passing of the worms or their ova is not available. Castor oil in full dose usually suffices for the threadworm. Santonin may be used for the roundworm, oleoresin of aspidium for the tapeworm.

Tennessee June Examination

Dr H W Qualls, secretary, Tennessee State Board of Medical Examiners, reports the written examination held in Knoxville, Memphis and Nashville, June 11-12, 1936. The examination covered 8 subjects and included 80 questions. An average of 75 per cent was required to pass. One hundred and eight candidates were examined, all of whom passed. The following schools were represented:

School	PASSED	Year Grad	Per Cent
College of Medical Evangelists		(1936)	83.1
Howard University College of Medicine		(1934)	86.4
(1935) 85.1 87.89 (1936) 87.4 89.3			
Harvard University Medical School		(1933)	85.3
University of Pennsylvania School of Medicine		(1935)	85.4
McHARRY Medical College		(1935)	84.1
(1936) 81.6 84.6 84.8 85.85 85.1 85.4 85.8 85.9

Book Notices

The Art of Treatment. By William R Houston A.M. M.D. F.A.C.P. Cloth Price \$5 Pp 744 New York Macmillan Company 1936

This new volume on therapeutics is arranged in seven books. In book I, called "The Art of Treatment," there are the following sounding titles: The Scope of Therapeutics, Surgical Treatment, Pharmacology, Therapeutic Thinking, Diagnosis, Honesty, Economics, and The Doctor as a Therapeutic Agent. Finally several pages, under the title Order of Presentation, tell just how what follows is to be arranged. There are eighty pages, all told, of this.

Book II is called "Patients Who Are To Be Treated Chiefly By Nursing Care," and its first six pages are devoted to a description of what is meant by this title. There then follow twenty-eight pages on the care of typhoid, which is offered as an example of nursing but in which it is difficult to separate the portions on nursing from discussions of venoclysis, "minus" decompensation, and many other things not all of which apply directly to the disease under discussion. Then in an interlude of about three pages the author enlarges on such titles as "What Is the Worth of Nursing Care?" "Trade Unionism," "Fidelity of Execution" and "Nurse as Home Teacher." The homily over, nursing care as applied to typhoid is resumed and continued with somewhat less prolixity through eight more pages. Immediately thereafter one encounters "Common Disorders," in which category there have been placed arbitrarily twenty three entities, among them those familiar everyday diseases: leprosy, plague and yellow fever. Apparently it is felt that any one who has read the preceding 128 pages will need little further guidance in handling these common things—at any rate little is offered in precise form in connection with the discussion of any of them. But still there is not an end of nursing care for book II approaches its close with sixteen pages in which pneumonia, erysipelas, scarlet fever, rheumatic fever and sepsis find respective places in a chapter entitled "Diseases Treated Chiefly By Nursing Care But in Which There Is Some Question of a Specific." The final eight and one half pages of the book are devoted to "Diseases Chiefly of the Nervous System."

Book III bears the title "Specifics" and considers the paratubercular, endocrine, deficiency and hematopoietic categories, together with a group of diseases treated by serums and antigens and another set of three "miscellaneous" conditions, which are acidosis, alkalosis and Asiatic cholera. Treatment is nowhere succinctly discussed here and in some instances the principal modes of therapeutic attack are not even fully indicated. For example, in the brief section on malaria the "standard" treatment is quoted from the 1918 report of the National Malaria Committee, and its worth in the light of present-day knowledge is then expounded as follows: "This very simple statement of the National Committee as to how malaria should be treated is one that might well be put in the hands of every layman who lives in a malarious district. It might be printed weekly in the county paper or even placarded on the barns and fences to the community's advantage. It is easy to see, however, how sure a dissemination of knowledge might put a doctor who is not quite sure of himself in a somewhat embarrassing position."

This standard treatment he may have used on plow hands and dock labourers to advantage, but when he is summoned to attend the big boss, who is already aware of the details of the standard treatment, it is quite natural for the doctor to feel that something more than the standard treatment is expected of him—some niceties and refinements of the therapeutic art which the common labourer could not command. Furthermore, the big boss very likely expects rather assiduous attention from the doctor, and what can the doctor do on his several visits, if the whole plan of treatment has been widely published and is known to everyone? All would of course be easy enough if the refinements in the treatment of malaria were better than the standard treatment. Unfortunately they are not so good and every departure from the standard treatment weakens the therapeutic attack on the disease." Not a single word is offered here indicating the existence of such a thing as treatment by shorter courses and smaller doses of quinine the plan of malaria therapy which several years ago gained the stamp of approval of the Malaria Commission of the League of Nations and is today advocated by all the world's foremost authorities in the treatment of the disease. Furthermore, what little there is in the text on plasmodium and atabrine is principally in the form of a somewhat facetious admonition against the trial of these new remedies.

Book IV turns to the nervous system again and presents "Conditions in Which the Chief Therapeutic Method Is Psychotherapy or Guidance." The author states that, if the febrile conditions are left out of account, one half the practice in internal medicine is in conditions lying within the realm of this title. So he devotes 239 of his 725 pages of text to book IV. Of course this just consists in going on and on—sometimes instructively, here and there amusingly, but on and on for a full third of the length of the book.

Book V is "Diseases Which Impose a Limitation upon Life as the Condition of Treatment", book VI "Disorders in Which Physiological Considerations Guide Treatment", book VII and last, "Conditions in Which Treatment Is Tentative and Experimental." There are two indexes, one a general index, which is completely inadequate, and an index of names, which is literally a listing of the names of men mentioned in the book and the page or pages on which such mention is made, fortunately the latter completely useless appendage occupies only two and one half pages. Bibliographic references are scattered throughout the book.

Dr Houston says that the design of his work is to encourage therapeutic thinking, one may doubt that he has succeeded in doing as much as that but certainly he has himself thought very ponderously and to read the present rambling record of his cogitations is at times an entertaining task. But young men in search of authoritative detail and practical guidance are not likely to find them here or apt to cherish the philosophic ripeness that is offered as a substitute.

Traitement chirurgical de la maladie de Basedow et des goitres toxiques Par L. Bérard professeur de clinique chirurgicale à la Faculté de médecine de Lyon et R. Peycelon. Paper. Price 40 francs. Pp 170 with 42 illustrations. Paris: Masson & Cie 1936.

American students of goiter will be interested in this excellent contribution to the literature based on thirty years of clinical and operative observations. They will appreciate the knowledge the authors have not only of the European but also of the American literature. The subject matter, as indicated by the title, is largely of a surgical nature and no attempt is made to discuss diagnosis in detail. The authors however, oppose the dual theory of hyperthyroidism as advocated by the Plummer school and consider exophthalmic goiter and toxic adenoma merely variations of the same disease. In support of this contention they assert that iodine favorably influences both types, a contention that has recently been disproved. Likewise, the authors contention that unfavorable results may occur in exophthalmic goiter from too large doses of iodine is questionable. The authors frankly admit that their mortality statistics of 4 per cent are higher than those reported by American writers. They offer a logical reason for this because many of their cases do not come to operation until the disease has been active for many years. Resection of the thyroid gland is considered the most successful treatment of exophthalmic goiter. The disease in older persons rarely attains the acute

stage it does in the young, and it is more easily cured and without as great a risk. Digitalis is used only in case of decompensation. Iodine is used in the preoperative and post-operative care and continued in gradually decreasing doses. Iodine has replaced the necessity for ligation and x-ray therapy. Patients are kept in bed at least a week before operation (a procedure now seldom used here). Subtotal resection of the gland similar to the method used in America is the preferred operation. The capsule is resutured after a rather radical resection and a midline drain is used. There is an excellent discussion of the surgical technic used in the various types of operations, which is well illustrated. Local regional anesthesia has superseded general anesthesia. The important complications, as hemorrhage, nerve paralysis and tetany, are carefully reviewed. In discussing the end results, the fact is pointed out that what some consider-as cures, others term improvement. The authors' statistics show a total of 84 per cent good and 58 per cent excellent results. Again they justly conclude that better results would occur if the patients came to operation sooner. The value of the metabolic rate is appreciated but the clinical criterion is more certain. There are chapters dealing with toxic adenoma and its surgical treatment, also with thyroid cardiac disorders and cancer. This book will especially interest American surgeons who desire to know the current continental opinions regarding the operative treatment of toxic goiter.

The Toxemias of Pregnancy By Dame Louise McIlroy DBF LLD MD Consulting Obstetrician and Gynaecological Surgeon Royal Free Hospital London. Cloth. Price \$5. Pp 353 with 19 illustrations. Baltimore: William Wood & Company 1936.

Dame McIlroy's views on the engrossing subject of the toxemias of pregnancy have always attracted commendatory attention from the American medical public. She has now elaborated and embodied certain of her earlier writings in this monograph, together with a comprehensive and discriminatory review and abstract of recent opinions. It is interesting to note that she considers the symptoms of toxemia as being due to disturbances in metabolism, discarding the idea of a specific toxin. Moreover, she embraces the current but still disputed opinion that vomiting or convulsions, for example, are not separate forms of toxemia of pregnancy but merely varying symptoms of metabolic disturbances associated, perhaps, with some deficiency in nutrition or some prepregnancy disease. The entire monograph is precisely the dignified and conservative type of exposition of this baffling subject that would be expected from Dame McIlroy's pen. It should be gratifying to us in this country to note the consideration and space she gives to the work of American investigators. The monograph is satisfactorily divided into sections, discussing in turn mortality rates from toxemia, theories regarding its causation, dietetic and nutritional disturbances in pregnancy, and the symptoms, the effects and the treatment of pregnancy toxemia. The text is made complete by a comprehensive bibliography. Throughout the book there is only one jarring note. This is the frequency with which various pharmaceuticals are recommended under their trade names or with the specification that the preparation of some particular firm be used. The book may be warmly recommended not only to the research worker but also to the practitioner, who will find its many suggestions regarding prevention and treatment especially useful.

Textbook of Gynecology By Wilfred Shaw MD FRCS FCOG Assistant Physician Accoucheur St Bartholomew's Hospital. Cloth. Price 18s. Pp 538 with 238 illustrations. London: J & A Churchill Ltd 1936.

Shaw states in his preface that "this book is intended for the use of students presenting themselves for qualifying examinations, and it may also be of service to practitioners." The author's intentions have been admirably fulfilled. Students will find in this textbook a straightforward exposition of each of the major subjects in gynecology. Ordinarily difficult topics such as pelvic anatomy and embryology are dealt with clearly and concisely, and are made interesting by timely mention of clinical points. Discussions are not interrupted by references to medical literature, moot points are passed over lightly. The doctrines set forth are sound and, with few exceptions, will be acceptable in this country. Practitioners will find the book of practical value. Emphasis is laid on the common disorders, the reader is taught to rely on himself, not on the laboratory, for diagnosis, the sections on treatment are excellent and give

definite, well tempered advice. Authors will find this book a model of good medical writing. The style is fluent, lucid and simple, the chapters are concisely organized and carefully integrated, the entire work is well proportioned and perfectly designed for its purpose. There are adequate illustrations, including good photomicrographs. The publisher's work is flawless. Items that might well have received more emphasis are the electrical cautery treatment of erosions, the use of the basal metabolism test in studying menstrual dysfunctions and sterility, the fitting of contraceptive diaphragms, the importance of curettage prior to x-ray treatment of myomas, and lymphogranuloma inguinale. American gynecologists may be astonished to find pain and cachexia listed among the four "main symptoms" of cervical carcinoma. Indeed, one gains the impression that biopsy of the cervix or of the endometrium is seldom necessary, a point of view entirely contrary to ours in this country. In conclusion, this excellent textbook can be strongly recommended to teachers, students and general practitioners. Specialists in gynecology will find it of little reference value, but it was not designed for them.

The Townsend Crusade. An Impartial Review of the Townsend Movement and the Probable Effects of the Townsend Plan. Paper. Price 25 cents. Pp. 93. New York: The Committee on Old Age Security of the Twentieth Century Fund, Inc. 1936.

Few, if any, proposals put before the American people in recent years have had so wide an emotional appeal or have so quickly enlisted vast multitudes of followers as has the Townsend plan. Dr. Townsend, then already retired and living near Los Angeles, lost most of his savings in the crash of 1929. So did many other elderly persons. Dr. Townsend had to resume the practice of medicine and was employed to supervise the care of indigent elderly persons in Long Beach. He is not an economist, but the plight of his patients set him to thinking of some way that would save elderly persons from penury after devoting their lives in the main to rearing families. He relates that he was finally moved to "do something about it" by the sight of three old women sifting through the contents of a garbage can—a picture which provoked him into indignation to the point of profanity. With a few dollars of his own money he ordered printed copies of the original petition for \$200 pensions and advertised for volunteers to circulate them. The growth of the movement was fast. Within fourteen months it was claimed by its supporters that the plan had the backing of 3,000 Townsend clubs, an average of nearly seven to each congressional district in the country, the clubs at that time having a minimum membership of 100 and a maximum up to 1,700.

The report contains sixty pages of readable material devoted to a review of the old age pension problem, the burden that a \$200 a month pension would place on all other citizens, the handicap thus placed on independent business and the huge overestimates made by the Townsend plan adherents as a result of using the wrong base for their figures on transactions taxable at 2 per cent. The committee states that the Townsend illusions are a sensational demonstration of the need for realistic thinking.

It is suggested that an increase in the present governmental assistance for the aged can be obtained in two ways and in these ways only: (1) an increase in the national income, which can come only from an increase in the production of goods and services, or (2) a further diversion to the aged of the income of the rest of the population.

The committee concludes from its study that anything like \$200 a month as an old age pension is utterly impossible with our present economic machinery. It seems however, that the pensions paid under existing legislation are not adequate, and that it should be possible to pay larger amounts.

Other important observations and conclusions are that forced expenditure such as is contemplated in the Townsend plan, would not increase the speed with which the income of the aged would be spent, forced expenditures would neither increase nor decrease purchasing power, to maintain the \$200 a month figure on which the hopes of many elderly persons are based would reduce a worker's salary by one eighth while the accumulated taxes would advance the price of common articles by one third, and, finally, an attempt to put the plan into operation would gravely aggravate the very ills which it seeks to cure. The report is readable and illuminating. It is a

timely analysis of the program, which is the basis of one of the largest present-day movements. It is impossible to predict what changes may be made in this crusade, but this report will enable interested persons better to understand the genesis of the movement, the underlying motives, the difficulties and failures exposed, and the general problem of aid to the aged.

Valor terapéutico de los extractos de corteza suprarrenal. Por J. Sánchez Rodríguez y Juan Barbudo. Trabajo laureado con el Premio Rodríguez Abaytua 1934 de la Academia Médica Quirúrgica de Madrid. Paper. Price 5 pesetas. Pp. 72. Madrid: Imp. Sáez Hermanos. 1935.

This monograph, including fifty-seven pages of text and a list of 352 references, presents a good compilation of literature on adrenal cortex extracts, assembled in the manner characteristic of many recent review articles in medical research and physiology. Under therapeutic applications of adrenal cortex extracts, reports on treatment of the following conditions are included: Addison's disease, gastroduodenal ulcer, ovarian insufficiency, intestinal intoxication, neuritis, infections, asthenia, muscular dystrophy, cancer, hyperthyroidism, cutaneous diseases, mental diseases and other disorders. Critical discussion of these reports is lacking. With twelve specific ailments and any number of additional conditions under the category of "other disorders" for which adrenal cortex extracts have been employed, usually with alleged benefit, it would seem that at last the elixir of life has been found or else we are dealing with a literature that bears close resemblance to the advertisements of a certain vegetable compound. The authors could have improved their publication by including a critical discussion of some of the remarkable inconsistencies (or absurdities) in the literature cited, e. g., hyperthyroidism has been alleged by some surgeons to be successfully treated by reducing adrenal function (partial adrenalectomy) while certain medical men have claimed similar benefit from adrenal extracts, which means increased adrenal function. The same paradox can be found in the literature on the treatment of gastric ulcer. Can it be that hyperthyroidism and gastric ulcer are related etiologically to hyperadrenalism in the surgical clinic and to hypo adrenalism in the medical clinic? Adrenal cortex extract appears to be endowed with Dr. Jekyll-Mr. Hyde potentiality, for it has been credited with capacity to increase the basal metabolic rate where increase is desirable (Addison's disease) and to decrease it when indicated (hyperthyroidism). In hypertension it has been reported to lower the blood pressure, while it raises the pressure in adrenal insufficiency. Of course, these seemingly inconsistent observations become quite credible if one accepts, without question, the claim that an adrenal extract produced remarkable improvement in a patient with Addison's disease who (according to a second report) apparently was dead two and a half months prior to the date of the reported improvement! The authors did well to avoid more than is included in their monograph. The literature is too bewildering. If and when adrenal extracts of uniform composition and activity become available and more reliable, well controlled experimental and clinical studies are made, the literature will lend itself better to consideration in book form. At present a monograph on adrenal extracts could best serve a useful purpose when limited to unbiased, fearless, critical consideration of existing literature. Such a book would constitute an interesting commentary on present-day endocrinologic "research."

Vitality and Energy in Relation to the Constitution. By T. E. Hammond, F.R.C.S. Surgeon, The Royal Infirmary, Cardiff. Cloth. Price 12s. 6d. Pp. 314. London: H. K. Lewis & Co. Ltd. 1936.

It is difficult to evaluate this book. On superficial reading it would be grouped among the many discursive contributions of clinicians which have little positive scientific or medical value. Dr. Hammond is certainly not widely read in the field of constitution, quite apart from the integrating fields of medicine. The text is not coherent, the case reports are sketchy. But with all these handicaps it reflects the intelligent observations of a surgeon who has watched his patients carefully and who is aware of the fact that our modern medicine with its emphasis on "rare cases and research" is somewhat lacking when it comes to the practical application of our vast store of scientific knowledge to the individual patient. Dr. Hammond feels the need of a wider comprehension of the individual. In his book there is no detailed inquiry into the organic character of his patients; there is no clinical investigation in the strict sense, rather the groping for a concrete definition of the

ing of constitution, vitality, tonus, physique and stamina—the various chapter headings used in the book. What Dr Hammond does do is to bring into focus a type of inquiry that is beginning to concern a larger group of physicians, for there are a number of similar books in the continental literature where the trend is definitely labeled as hippocratic. But, while the Greek school was (considering the limitations) always precise and clear, many of these books are rather nebulous and uncertain, and consequently it is doubtful whether medicine will be advanced by such contributions, much though one may appreciate the underlying point of view and the underlying motive. “That things happen is nothing that they should become known, everything” (Friedell). Hammond’s book discusses things that happen clinically, from an intelligent point of view, and one that may be new to many, unfortunately it contributes nothing concerning the “why” of the happening.

Report on the Works Program. Harry L. Hopkins, Administrator, Works Progress Administration, Division of Research, Statistics and Records. Paper, Pp 106 with illustrations. Washington, D. C. Supt. of Doc. Government Printing Office, 1936.

This is a descriptive and statistical account of the Federal Works Program. The works program is a consolidation of the emergency work activities financed by funds appropriated under the Emergency Relief Appropriation Act of 1935. This act gave expression to the policy that in place of direct relief, aid for the unemployed was to take the form of useful public work. Under the program, 3,850,000 persons were employed at the end of February 1936. Some of the activities of the program described in this report are the construction of farm-to-market roads which will provide improved highways for millions of farmers—these road projects represent a value of \$160,000,000; the construction or repair of 5,300 school buildings, the erection or repair of 4,200 public buildings (excluding schools), the construction or improvement of 5,000 parks and playgrounds; the installation or repair of 6,300 water and sewer system plants, the completion of 328 airport projects, the installation or repair of 130 electric utilities systems, and assistance to 289,000 youths of high school and college age to enable them to continue their studies and to keep them out of the present overcrowded ranks of labor. There has been undertaken a nation wide cultural program to provide suitable employment to those of the relief population normally engaged in artistic endeavor. Writing, music, painting and drama have always been recognized as vital aspects of civilized life. Many who devote themselves to these cultural activities do not have the physical stamina to engage in the more arduous labor of construction. The Public Works Administration has issued grants and loans of approximately \$480,000,000. Funds provided locally account for some \$260,000,000, or 35 per cent of the total cost of projects, which was \$743,000,000 at the time this report was prepared. Under the Resettlement Administration more than 333,000 destitute farm families in all parts of the country (as of Nov. 30, 1935) were being assisted in readjusting their debts, obtaining necessary capital goods and the like. Plans are being perfected for the transfer of 20,000 families from submarginal lands to places better suited for agriculture. Those who are interested to learn something of the complexity and magnitude of these activities of the Federal Works Progress Administration program will find much material for serious reflection in this report.

Conflicts Between Preschool Children. By Arthur T. Jersild and Frances V. Markey. Child Development Monographs, Monograph No. 21. Paper. Price \$1.80. Pp 181. New York: Bureau of Publications, Teachers College, Columbia University, 1935.

This is one of the series of monographs on child development and brings “factual information to bear on the time-honored subject of the social versus the individualistic nature of man.” The material was derived from an observational study of the aggressive, resistant and hostile behavior of children between 2 and 4 years of age as seen in the nursery schools and kindergartens. The experimental conditions were varied and well controlled and the authors’ observations are of great interest from the sociological as well as psychologic aspects. The monograph is informative and provocative. There is a wealth of objective data which should aid our understanding of behavior patterns, both natural and culturally determined.

Bureau of Legal Medicine and Legislation

MEDICOLEGAL ABSTRACTS

Compensation of Physicians. Payment on Account as Tolling Statute of Limitations.—The plaintiff, a physician, brought suit against the defendant in July 1935, in the city court of Shreveport, La., for \$125 allegedly due for professional services. A balance of \$68 was due him for services rendered to the defendant and members of his family up to the close of 1931. On March 15, April 12 and 23, and May 18, 1932, he rendered additional services, for which a charge of \$9 appeared on his books. On Sept. 6, 1932, the defendant paid the plaintiff \$10. For services rendered thereafter the plaintiff’s books showed additional charges of \$58. The defendant contended that the physician could not now maintain a suit for the \$68 due for services rendered up to the end of 1931 because in Louisiana, by statute, actions on oral or implied contracts must be instituted within three years from the accrual of the cause of action. The physician, however, argued that the payment of \$10 made Sept. 6, 1932, interrupted the running of the statute, since it operated as an acknowledgment of the debt and as a payment on account, and the statute should be computed from that date. The \$10 paid by him, the patient answered, was intended only to pay for the services rendered by the physician on March 15, April 12 and 23, and May 18, 1932, and was not intended to be used as a credit against that portion of the account which he now contends is barred by the statute. From a judgment in favor of the physician, the patient appealed to the court of appeal of Louisiana, second circuit.

A partial payment on an account, said the court of appeal, is an acknowledgment of liability on that account and operates to interrupt the running of a statute of limitation or prescription. Therefore, if the payment made by the defendant on Sept. 6, 1932, was intended to be a credit on the whole account to that date, the suit, being instituted in July 1935, has been timely instituted. The court then undertook to dispose of the defendant’s contention that that payment was made for the restricted purpose of covering the services rendered by the plaintiff on March 15, April 12 and 23, and May 18, 1932. A perusal of the account, the court said, shows that the defendant paid \$10 on account in December and in seven other months in 1931. He made no further payment until Sept. 6, 1932, when the payment in question was made. On the face of things, it would appear that this last payment was merely in keeping with the course he had followed in making the eight prior payments. There was as much reason that this payment should have been intended to apply as a credit on the entire account as there was that the eight other similar payments should have been so intended. The court also deemed it significant that the \$10 payment made in September 1932 overpaid by \$1 the charges the defendant claimed it was intended to pay. The court further thought it unreasonable to believe that the physician would have accepted the payment under the restrictions claimed by the defendant. It concluded that the payment in question was made without any restrictions whatever as to its application as a credit on the entire account, that it operated as an acknowledgment of liability on the entire account and interrupted the running of the prescriptive period. The judgment in favor of the physician was accordingly affirmed.—*Williams v. Plumb (La.)*, 166 So. 896.

Workmen’s Compensation Acts. Tuberculosis Allegedly Activated by Oil Field Gases.—The claimant, an oil field worker in the course of his employment, to “thaw out” some pipe connections poured boiling water on them. When the water struck the connections and crude oil, gas or vapor arose. The claimant began to choke and gasp and lost consciousness. He was forced to quit work for the day and, although he returned to work on the next day, the third day he quit his work permanently because of his physical condition. He claimed to be suffering from active pulmonary tuberculosis and alleging this to be the result of the industrial accident, he instituted proceedings for workmen’s compensation before the

Oklahoma industrial commission Medical witnesses, on behalf of the worker, testified that prior to the industrial accident he was affected with dormant tuberculosis, of which he was not aware and which did not then constitute a disability, and that the choking, gasping and inhalation of vapors or gases while he was attempting to thaw out the frozen connections changed his tuberculous condition from one of dormancy to one of activity. To review an award in the claimant's favor, the employer brought an original proceeding in the Supreme Court of Oklahoma.

The employer challenged the competence and the sufficiency of the medical testimony adduced by the claimant to show the causal connection between his alleged disability and the industrial accident. On behalf of the employer, a medical witness, who was a specialist on chest diseases and who had also made a special study of oil field gases and vapors testified before the industrial commission that the worker did not have tuberculosis but was suffering from emphysema and other associated complications and that the alleged accident, if it occurred at all had nothing to do with the claimant's condition. He further testified that oil field gases were not productive of tuberculosis. The employer argued that since all the medical witnesses who testified on behalf of the claimant were general medical practitioners, and not specialists, they were not qualified to express an opinion concerning the causal connection between the present condition of the worker and the industrial accident. Ordinarily, said the Supreme Court of Oklahoma the difference between the testimony of an ordinary physician and a specialist in a given medical field is one which relates to the weight of the evidence and not to the competence thereof. After an examination of all the medical testimony, the court was unable to agree with the contention of the employer. A witness who testified on behalf of the worker stated that, while he was without detailed technical knowledge of the chemical contents of different oil field gases, he was sufficiently familiar with them to know that some were irritating and that some were not, that regardless of whether the gases inhaled by the worker were irritating or nonirritating they might, and in this case did, in his opinion, produce the worker's disability, and that nonirritating gases could reduce the oxygen content of the air, thus causing the victim to gasp and choke and thereby activate dormant tuberculosis. The court believed that the conclusions announced by the physicians who testified on behalf of the worker presented a question of fact for the industrial commission which was determined in the claimant's favor and it refused to announce a rule of law that would compel a fact-finding body to disregard the testimony of a general practitioner of medicine merely because it is opposed by that of a specialist in a given field. However, the award in favor of the claimant was reversed because of error committed by the commission in computing the amount of compensation to which the worker was entitled. The case was remanded to the commission for further proceedings.—*Skelly Oil Co v Rose (Okla.)*, 55 P (2d) 1019

Narcotics Entrapment of Physician, Prescribing in "Good Faith" Construed—The defendant, a licensed physician and pharmacist who operated a drug store, was convicted of violating the Illinois narcotic drug control law and was sentenced to one year imprisonment. He appealed to the Supreme Court of Illinois.

The evidence on behalf of the prosecution tended to show that the prosecuting witness had purchased morphine regularly from the defendant for three or four months prior to April 10 and that the defendant had never on any occasion examined him. In making the purchases, the prosecuting witness testified, he informed the defendant that he was getting the narcotics for his wife who was an addict. On April 10, according to the evidence, the prosecuting witness, pursuant to prearrangements with two police officers purchased from the defendant \$3 worth of morphine tablets, with money supplied by the officers. The morphine purchased was delivered to the officers. Two days later, the witness purchased, pursuant to similar prearrangements, an additional supply of morphine tablets from the defendant and paid for them with a dollar bill, the serial number of which had been noted. This supply was likewise delivered to the officers, who were waiting outside. The arrest of the defendant followed immediately and the dollar bill was found

in his possession. The defendant testified, on the other hand, that he had never sold narcotics to the prosecuting witness prior to April 10 and that on that day he examined the witness and detected a mitral murmur, a "hard" pulse, and a cough associated with restlessness and shakiness, that he sold him twelve "sedative tablets," that on April 12, on being informed by the prosecuting witness that he had lost the supply of tablets sold him on April 10, he sold additional tablets without further examination.

The defendant contended, among other things, that he was unlawfully trapped. Entrapment, said the court, constitutes a valid defense if officers of the law inspire, incite or lure a defendant to commit a crime which otherwise he had no intention of committing. Officers may, however, legally afford opportunities for the commission of a crime and may use artifice and stratagem to catch those actually engaged in criminal enterprises. In the instant case, the court said, the officers did no affirmative act to incite or persuade the defendant to sell the morphine. They merely afforded him an opportunity to violate the statute. In doing so, they acted within their legal rights.

The narcotic drug control law was not unconstitutional, the court said, in providing that "a physician, in good faith and in the course of his professional practice only, may prescribe, administer, or dispense habit forming drugs." The use of the phrase "good faith" did not result in ambiguity and uncertainty. In *Crouch v First Nat Bank* 156 Ill 342, 40 N E 974, "good faith" was held to mean "honest, lawful intent," and in *McConnel v Street*, 17 Ill 253, it was held to mean "the opposite of fraud and bad faith." The phrase, said the court in the present case, has a definite and well understood meaning. It is free from ambiguity and its use does not violate the due process clause of the state and federal constitutions.

The trial of the defendant began on the day that the narcotic drug act was repealed and on which the uniform narcotic drug act became effective. The defendant was sentenced under the former act. Because the uniform act reduced the penalty for a first offense, the court was of the opinion that the trial court should have permitted the defendant to elect under which law he desired to be sentenced, as authorized by an Illinois statute. The judgment was therefore reversed and the case remanded to the trial court to accord that opportunity to the defendant.—*People v Guaghata (Ill.)* 200 N E 169

Current Medical Literature

AMERICAN

The Association library lends periodicals to Fellows of the Association and to individual subscribers in continental United States and Canada for a period of three days. Periodicals are available from 1926 to date. Requests for issues of earlier date cannot be filled. Requests should be accompanied by stamps to cover postage (6 cents if one and 12 cents if two periodicals are requested). Periodicals published by the American Medical Association are not available for lending but may be supplied on purchase order. Reprints as a rule are the property of authors and can be obtained for permanent possession only from them.

Titles marked with an asterisk (*) are abstracted below.

Advantages of Vacuum Dried Complement for Use in Routine Wassermann Reaction. F. Boerner and Marguerite Lukens, Philadelphia—p. 272.

"Depepsinized" Human Gastric Juice in Treatment of Pernicious Anemia.—Fitz-Hugh and Creskoff decided to review some of Greenspon's experiments. In summarizing their observations they state that in three patients in the relapse phase of pernicious anemia intramuscular injections of "depepsinized" concentrates of fasting gastric juice obtained from themselves failed to produce significant reticulocyte responses.

In one patient the oral administration (of 1,000 cc in two doses) of "peptically inactivated" normal fasting human gastric juice failed to produce a truly significant reticulocyte response (i. e., no greater reticulocytosis than the authors have observed to occur spontaneously in relapse phases of pernicious anemia).

In two patients the intramuscular injection of depepsinized normal fasting human gastric juice concentrates failed to produce significant reticulocyte responses. Thus the authors' experiments fail to substantiate the results and hypotheses of Morris and his co-workers and of Greenspon as regards the sole importance of intrinsic factor. They think that, while entirely negative their experiments constitute no grounds for disbelief in Castle's fundamental "conditioned deficiency" concept of pernicious anemia. They believe that Greenspon, although possibly right in his conclusion that peptic digestion destroys "intrin," has not proved the rest of his hypothesis regarding the complete unimportance of Castle's "extrinsic" factor and "interaction product" mechanisms.

Effect of Aminopyrine on Blood Cells.—Rawls says that his first two cases of agranulocytosis attributed to aminopyrine medication were observed in 1933. Since that time he has

observed two more cases in private practice and two others in consultation. He undertook the present study to determine (1) the frequency of the occurrence of agranulocytosis in patients treated with aminopyrine and (2) any change in the red and white blood cell counts, or polymorphonuclear counts of patients who were treated with aminopyrine but did not develop agranulocytosis. This was done in an effort to determine whether agranulocytosis might be due to drug idiosyncrasy or whether leukocytic changes occur with any regularity during the course of aminopyrine medication. The author states that during the past three years more than 100,000 tablets of aminopyrine or aminopyrine mixed with magnesium carbonate were administered to 400 patients in the clinic and in private practice. Of these, four (1 per cent) developed agranulocytosis and three of them died. Although this incidence is small, it is important because of the high mortality rate. The author further presents an analysis of the blood pictures of 100 cases (exclusive of those in which agranulocytosis developed). When this series is considered as a whole, the only change noted is a significant increase in the red blood cell counts. When, however, the groups are analyzed separately, there is a definitely significant increase in the red blood cell counts in males with rheumatoid arthritis, a significant increase in the white blood cell counts of the females with rheumatoid arthritis and a possible significant decrease in the polymorphonuclear counts in females with miscellaneous arthritis. It is interesting to note that the red blood cell counts are increased in all groups and that no definitely significant hematologic decrease occurred in any group. From this it might be maintained that agranulocytosis developing during the course of aminopyrine medication must be due to a hypersensitivity or idiosyncrasy.

Cervical Dilatation in Dry Labor.—How does the cervix open, and what is the role of the amniotic sac in labor, are questions that according to King have been disputed since the beginning of scientific obstetrics. He made investigations on 1,001 uncomplicated full-term parturitions occurring in 1,621 obstetric admissions. Of these, 40 per cent enjoyed intact membranes until complete dilatation and were used as controls. Thirty-one per cent spontaneously ruptured the membranes before the onset of regular pains at twenty-minute intervals and were classed as dry labors. The remaining 29 per cent was made up of those whose membranes were intact only to a dilatation of from 4 to 7 cm (11 per cent by spontaneous rupture and 18 per cent by deliberate rupture). No light was thrown on the etiology of rupture of the membranes, although it occurred disproportionately more often in primiparas. The occipitoposterior position was not a factor. The length of labor was studied from four points of view. There was a larger

percentage of prolonged labors in the control group than in the dry and partially dry groups. The cumulative distribution curves of percentage completed labors at two-hour intervals was most favorable for completely dry labors and least favorable for the "wet" labors, the partially dry labors falling between. In the partially dry labors there was a positive rather than a negative correlation between the length of the "wet" portion of the labor and the total length of labor. The statistically significant averages of the length of labor showed dry labor to be shorter than the controls by 20 (± 0.25) hours for primiparas and 24 (± 0.24) hours in multiparas. Concerning the safety of labor in the absence of the membranes, the author says that the incidence of forceps intervention was 163 per cent in the control group, 106 per cent in the dry labor group and 126 per cent in the partially dry labor group. The morbidity was essentially the same in all groups, i. e., 62 per cent in the controls, 55 per cent in the dry labor cases and 67 per cent in the partially dry labors. There was a slightly lower incidence of cervical lacerations in the dry labor group than in the controls, with the partially dry labors falling between. The fetal mortality was unaffected by rupture of the membranes. An exhaustive review of the literature disclosed that reports in the last fifteen years amply confirm the foregoing observations. These results offer support to the explanation of cervical dilatation suggested by Dewees, that in labor the cervix is gradually retracted over the head by muscular action alone. On the other hand, that dilatation is accomplished by the hydrostatic wedge, a theory which has been disputed repeatedly since the eighteenth century, appears to be incompatible with the results of this experiment, since the membranes proved to be unnecessary for a safe, easy and short labor.

Pelviccephalography.—According to Ball, the information obtained from the usual methods of roentgen pelvimetry and fetal cephalometry has been a disappointment to many obstetricians and radiologists. The reasons for this are probably numerous, but mainly it has likely been due to a failure to consider the third dimension. The relationship between the fetal cranium and the birth canal is best visualized by volumetric comparison. The problems in the mechanism of labor cannot be reduced to the simplicity of comparing a fetal skull diameter to a pelvic diameter. It is seldom possible by external means to obtain any definite idea of the mass volume of the fetal skull. Therefore a roentgenographic method that will measure the three dimensional size of the fetal skull and the birth canal should be of aid to the obstetrician. The author directs attention to his earlier description of such a method, which required only two exposures and does not require any measurements of the patient. All data are obtained from roentgenograms in the anteroposterior view with the patient in the supine position and in the lateral view with the patient in the lateral recumbent position. If preferred, the exposures may be made with the patient standing. Also, by one additional exposure in the anteroposterior view the films may be examined stereoscopically. The accuracy of the method has been within 5 per cent error for linear measurements and 10 per cent for volumetric estimations. All types of presentations are measurable and the examination may be done with accuracy from the thirtieth week of gestation. In breech presentations additional exposures are, of course, necessary to measure the fetal skull. The volume of the fetal cranial skull is determined by measuring the circumference of the film images. The magnification of the film image is corrected by a calculator, thereby eliminating any mathematical computation. To obtain measurements conveniently, a correction chart was mounted on a dial and the pointer geared to a calibrated contact wheel similar to a map measure. The fetal skull volume is compared to the volume capacity of two pelvic diameters, the true conjugate and the bi-ischial spine. Following the interpretation of volume ratio, the importance of the architecture of the pelvis in the mechanism of labor in marginal sizes only is discussed briefly. The frequency of occurrence of different type pelvis with presentation and position of the fetus near term or in labor in the native Southern white and Negro is tabulated. The absolute rate of increase in volume of the fetal cranium in utero as obtained from roentgenographic data is presented.

Ergot in the Puerperium.—In view of the divergent opinions on the importance of ergot, Beecham studied the morbidity, involution and puerperal bleeding in 551 postpartum

cases on three different ergot regimens in the Kensington Hospital for Women. Every patient received an ampule of solution of posterior pituitary and ergot at the completion of the second stage of labor. The first 100 patients received no oxytocic medication during their stay in the hospital. A series of 351 patients received fluidextract of ergot, U. S. P., starting when the patient was taken to her ward bed. Here she received 1 drachm (4 cc.) every four hours for six doses, and then three times a day for four days. In the third group of the series, 100 cases, a solution of ergonovine was administered in the same way as the fluidextract. It was found that lochia rubra was more persistent in patients receiving no form of ergot during the puerperium. Subinvolution occurred in much higher percentage (41.4 per cent) in nonergot cases than in fluidextract cases (13.2 per cent) and was completely absent in the ergonovine series. A satisfactory puerperium was observed in 85 per cent of patients receiving no oxytocic drug, in 87.8 per cent of patients receiving fluidextract of ergot U. S. P. and in 98 per cent of patients treated with ergonovine. There was less striking difference in the morbidity percentages in the three groups than in the figures showing degree of bleeding and subinvolution. Thus ergot appears to be a useful and necessary aid to a normal puerperium, preferably in the form of a preparation of known ergonovine content.

- *Significance of Small Variety Endamoeba Histolytica Bertha Spector Chicago—p. 813

Significance of Small Variety Endamoeba Histolytica.—According to Spector, *Endamoeba histolytica* is a species composed of distinct strains differentiated by the size of their cysts. Endamebas producing small cysts differ from

those producing large cysts physiologically, culturally, immunologically, clinically and in pathogenicity for lower animals. The trophozoites of *Endamoeba histolytica* producing small cysts are usually smaller and not so motile as those producing large cysts, and they do not ingest red blood cells. Bloody mucous stools in acute cases of amebic dysentery usually show quite large and very motile trophozoites, whereas the trophozoites found in soft stools in mild cases of amebic dysentery and carriers are usually smaller, approaching those giving rise to the small variety *Endamoeba histolytica* cysts. *Endamoeba histolytica* producing small variety cysts differs culturally from the *endamoeba* producing large variety cysts. They grow infrequently (from 5 to 8 per cent) and with greater difficulty in Cleveland and Collier's medium, in which the large variety grows readily and luxuriantly. In the author's experience, cultures for *Endamoeba histolytica* from bloody mucous stools in active cases of amebic dysentery were positive in 100 per cent of the cases (forty-nine cases), but only about 95 per cent of the cultures of stools from carriers of the large variety *Endamoeba histolytica* were positive (thirty carriers). These figures are of clinical patients seeking medical care and are higher than those of food handlers, some of whom take amebicides before coming for examination in order to get a negative report. Arsenic was found in some of the stools that showed large variety *Endamoeba histolytica* cysts which failed to grow in culture. The cultures of the small variety *Endamoeba histolytica* must be subcultured every twenty-four to forty-eight hours, whereas those of the large variety need not be subcultured so frequently—every forty-eight to seventy-two hours is sufficient. *Endamoeba histolytica* producing small cysts differs immunologically from the *endamoeba* producing large cysts. It fails to give positive complement fixation when the antigen prepared from the sediment of cultures of *Endamoeba histolytica* producing large cysts is used in tests with serum from patients infected with the small variety *Endamoeba histolytica*. There is a difference of opinion as to whether *Endamoeba histolytica* producing the small cysts is pathogenic. The symptoms are much milder than those caused by the large variety, yet they seem to be typical and are eliminated on specific treatment, especially if the symptoms are of short duration. Until more is known about these organisms, infected persons showing symptoms should be treated. In the author's experience, liver and lung abscesses have not been produced by the small variety *Endamoeba histolytica*. In none of her cases of amebic liver or lung abscesses was she able to find small cysts in the stools, whereas in every such case the large variety *Endamoeba histolytica* had been found. Experiments on the pathogenicity for lower animals are still in progress.

High Carbohydrate Diets in Pulmonary Tuberculosis

—In studying a series of thirty-five patients Freilich and Coe increased the regular diet of 1,600 calories by 800 calories in terms of Karo syrup and Dyno sugar (dextrose). Thirty-three of these thirty-five patients were definitely benefited by this procedure. Patients who had been gaining in weight before the experiment began had a greater weight increase during the experiment; patients who had been losing weight before the experiment began to gain in weight, stopped losing, or lost less than previously; those who maintained a stationary level before the experiment began gained weight during the experiment. Two of the thirty-five patients showed no change. Twenty-six of these patients lost weight in the month after the experiment, whereas six patients continued to gain, two went home, and one did not lose or gain. All the patients showed a high toler-

ance for the Karo syrup and the Dyno without any evidences of gastro-intestinal upsets. No glycosuria was present in any of these patients. The blood sugar was within normal ranges before and after the experiment. Karo syrup or Dyno, used alone or in combination, showed no difference in the results obtained. The authors feel that the extra carbohydrates were beneficial to the patients and form a necessary part of the dietary treatment of pulmonary tuberculosis.

Simple Method for Preparation of Durable Anatomic Specimens—The Mettlers fix the specimen in solution of formaldehyde, wash it in water and dehydrate to 95 per cent alcohol, transfer it to benzyl alcohol until saturated, place it in saturated solution of Bakelite resin XR 6787 dissolved in 50 per cent benzyl alcohol and 50 per cent glycerin at 65 C, place it in an incubator at 50 to 60 C until the solution changes to a mushy white mass of a consistency resembling farina, remove the specimen from the mass, rinse it off with hot water, meanwhile brushing excess solid off with a moderately stiff brush, and allow it to dry. If the specimen is a gross cross section, the surface should be sandpapered smooth and the specimen coated with a layer of Bakelite resin XR 7403. When returned to the oven for forty-eight hours, a glasslike surface will result. After suggesting modifications for certain types of specimens, the authors stress that any of the specimens thus prepared can be stored without danger in drawers, hung on walls or put on shelves. They are not affected by dampness or warmth and are much more durable than composition models.

Diagnosis of Silicosis—Gardner thinks that, regardless of the history of exposure to dust, a diagnosis of silicosis should not be made until generalized discrete nodular shadows are visible in the lung fields. Large localized shadows suggest complicating infection but there is a conglomerate type of simple silicosis that occurs in the absence of active infection. It may result from pulmonary damage by previous infection that has healed. It can be differentiated from active infection only by careful clinical study and by repeated roentgenograms to exclude change in the character and size of the lesion. The silicotic lung may exhibit the usual manifestations of tuberculosis, superimposed on a background of generalized nodulation, more common are the massive foci of consolidation due

to silicotuberculosis. These may be situated in the upper parts of the lung, where they result from reactivated apical foci of tuberculosis, but frequently they occur in the middle or lower part of the lung. They consist of a very chronic combination of tuberculosis and silicosis progressing simultaneously in the same area. They give rise to much less pronounced symptoms of intoxication than tuberculosis alone. More acute forms of tuberculosis, aspiration disease and miliary tuberculosis occur, but they are not very common. Nonsiliceous dusts are generally responsible for an exaggeration of the linear markings of the lung. As far as known, the slight perilymphatic reactions responsible for them do not interfere with pulmonary function and they do not alter the native susceptibility to tuberculosis. Asbestosis is not so well understood. The roentgenogram shows a diffuse haziness of the lower lung fields and later a very fine uniform stippling. Whether chronic pleurisy, increased linear markings and conglomerate shadows are due to the dust, to secondary changes incident to collapse of the lobules, or to complicating infection, has not been definitely settled. The appearance of a tuberculous lesion in the asbestotic lung is apparently not modified. There may be some tendency toward chronicity.

Macrocytic Anemia in Lesions of Bowel—Butt and Watkins point out that a variety of conditions are often accompanied by a morphologic blood picture resembling that of pernicious anemia. Conspicuous among these conditions are instances in which the intestinal tract is involved in some disease process. In seven cases of proved ileitis of the terminal portion of the ileum there were six instances of macrocytic anemia, and in the remaining case the anemia was of the microcytic hypochromic type. Apparently the macrocytosis was not dependent on the degree of involvement of the ileum because the extent of involvement of the ileum was as great in the case in which microcytosis occurred as it was in the remaining six cases. In the six cases in which macrocytic anemia was present, the erythrocytes were well filled with hemoglobin and closely simulated those found in cases of pernicious anemia. However, there was but little poikilocytosis as compared with the degree usually seen in pernicious anemia. Four patients who had an ulcer of the ileum also had hypochromic anemia. In one of these cases the anemia was of the macrocytic hypochromic type, in two cases it was of the normocytic hypochromic type, and in the remaining case it was of the microcytic hypochromic type. Commenting on their observations, the authors say that since the macrocytosis and anemia disappeared following operation in this series of cases it would not seem essential to treat such an anemia with materials effective in the treatment of pernicious anemia. It seems to them, however, that for good therapeutic results such preparations should be used and preferably by the parenteral method, as this should result in a rapid response of the blood to normal. The possible coexistence of pernicious anemia should be kept in mind and in cases in which the clinical observations support a diagnosis of pernicious anemia the treatment must be continued after operative procedures. The most common symptom in this series of cases was cramping abdominal pain. The authors wish to emphasize that this symptom, particularly in the presence of macrocytic anemia without symptoms of pernicious anemia, strongly suggests a lesion of the ileum.

Endolymphatic and Associated Ducts in Man—Anson and Nesselrod show that, although numerous studies have dealt with the nervous portions of the membranous labyrinth, few have been concerned with the structure of the non nervous areas of the epithelial ducts. Two portions of the duct system have of late received attention, the slitlike communication of the endolymphatic duct with the utricle and the rugose wall of the endolymphatic duct itself. This study is concerned with the utricular and the endolymphatic duct in man, and particularly with the morphologic features of the ducts that can be studied advantageously with the aid of wax plate reconstructions. Several investigators have shown conclusively that the endolymphatic and related ducts in mammals are complex channels differing in many important respects from the conventional descriptions. The slitlike character of the utricular communication with the endolymphatic duct has been observed to be a striking feature of the duct system, this communication, as has been pointed out by others, is bounded on one aspect by a fold or "valve" (Bast), which anatomically at least is similar to other mechanisms in the body known to be valvular in function. The several dilatations of the endolymphatic duct are observed to be constant features, unlike the usual picture the endolymphatic duct is considerably enlarged to form a sinus like space medial to the utricular fold, as it proceeds distally within the vestibular aqueduct, the duct at first narrows and then expands into a second sinus-like space the walls of which are deeply plicate, these plicae are composed of epithelium over a substratum of loose, vascular connective tissue. The remaining part of the duct is marked by a decided narrowing and, next a distal swelling in the region commonly termed the endolymphatic sac, here the plications may be taller, but the underlying connective tissue is much less vascular than that in the region of the intermediate dilatation. In agreement with the interpretation of Guild, the authors believe that this system of folds answers the anatomic requirements of a resorptive mechanism for the endolymph. Suggestions are offered for a more descriptive terminology—seemingly needed to designate the specialized portions of the endolymphatic duct described in the recent literature.

Thrombosis of Aorta and Coronary Arteries—Clark and his associates thought that in the study and evaluation of the 'fibrinoid' lesions in thrombosed arteries it would be of aid to examine the intimal plaques of atherosclerosis and syphilitic aortitis in nonthrombosed vessels, for in such plaques the earlier stages in the development of this lesion should be seen. The observations were compared with those made in a study of nine parietal aortic thrombi. They could find no evidence to support the view that the fibrin-staining material in the plaques of coronary arteries represents altered or necrotic fibrous tissue. As in the plaques of atherosclerotic and syphilitic aortas such fibrin staining masses either represent the remnants of an organizing surface deposit of fibrin or are due to the penetration into the plaque of blood elements.

Alcohol and Glycerin in Treatment of Pyogenic Infections—Wood says that a report by McKim in 1927 drew his attention to the use of alcohol in dehydrating the tissues in infections of the hand and induced him to put the idea into practice, particularly in infections of the tendon sheaths. Glycerin seemed to be the logical agency through which to continue dehydration, lessen the possibility of the dressing adhering to the tissues and keep the wound free from contamination. After trying various percentages of glycerin from 100 per cent down, the diluent being rubbing alcohol, a combination of equal parts of glycerin and alcohol has been found the most satisfactory for general use. The general method of application of this treatment is as follows. In surface infections when only the skin and subcutaneous tissues are involved:
1 Incision is avoided until pus is localized and circumscribed
2 The area is cleansed with alcohol
3 A few layers of sterile gauze to cover all the edematous area completely are soaked in glycerin and rubbing alcohol, equal parts, and laid on the affected area. This is covered with a thin layer of absorbent cotton and lightly bandaged with an open-woven gauze bandage. An additional amount of glycerin and alcohol may then be poured over the area at once. No waterproof covering is used
4 In the case of a limb, it should be splinted or rested if a hand or arm it should be carried in a sling
5 The patient is given prescriptions for lotion 1, which is glycerin and alcohol equal parts, and for lotion 2, which is straight rubbing alcohol. Instructions are given to apply a small amount of lotion 2 every two to three hours, or more frequently in hot weather when evaporation is more rapid
6 The whole dressing is removed and replaced every twenty-four hours, early in the treatment, although an interval of two to three days may elapse without any particular loss to the effectiveness of the treatment
7 Careful instructions are given that the dressing must not be removed to make the applications and that no water be applied to the dressing. Should the dressing become moistened with water as frequently happens in hands, a larger quantity of lotion 2 should be immediately poured over the dressing. When the dressings are being changed, scrupulous care must be taken not to squeeze the inflamed area. As indicated by case reports, the author employed this treatment successfully in infected

lacerations, infected amputation of finger, carbuncle of the cheek, infected discharging sinus following operation, noma, infected traumatic bursitis, cellulitis and other conditions

Autogenous Serum Treatment of Narcotic Addiction—Black says that a new treatment for narcotic addiction has been gaining increasing popularity throughout the Orient during the past few years. The treatment was originated in Java by Dr Modinos and consists of the subcutaneous injection of autogenous serum taken from a blister raised with the aid of a cantharides plaster. It is based on the theory that there is an antidotal toxic substance in the serum of addicts. It has a remarkable effect in reducing the withdrawal symptoms and the craving for the drug in those addicted to opium, morphine and heroin. The author does not know whether it has been tried in cases of addiction to cocaine or other drugs. On admission the patient is given a physical examination, and his cooperation is solicited. An estimate is then made of the amount of narcotic he has been taking, and he is given enough tincture of opium by mouth on the first day nearly to equal his customary dose. A plaster is then prepared by taking a 4 inch square of adhesive plaster, to the center of which is applied enough emplastrum cantharidin B P to make a circle 1½ inches in diameter and about one-sixteenth inch thick. The skin of the upper abdomen is cleansed with alcohol and the plaster applied. The patient is warned to avoid breaking it, and it is left in place from eighteen to twenty-four hours. It causes some pain. When sufficient fluid has collected in the blister or, in any case, at the conclusion of twenty-four hours, the blister fluid is taken up in a syringe and injected subcutaneously. The amount of fluid obtained from a blister varies greatly. The author injected as much as 10 cc of blister fluid, but a dose as large as this sometimes causes some reaction and discomfort. Probably the optimal injection is about 5 or 6 cc., though even as little as 1 cc has an appreciable effect. The blister site heals in a few days without trouble. The author found a 5 per cent solution of tannic acid effective as a dressing. Another blister is applied the day after the injection, and further ones every second or third day as required. The author has not found it necessary to give more than four injections of blister fluid to any one patient. In the meantime tincture of opium is continued in rapidly decreasing doses, combined with tincture of belladonna and tincture of nux vomica. Phenobarbital or pentobarbital sodium is given to assist in obtaining sleep. The bowels are kept open with compound cathartic pills, three or four of which are needed in a dose at the outset of treatment. In every case the injections were followed in a few hours by a lessening of discomfort and a decrease in the craving for the drug. Some of the patients refused opium after their second injection.

Raw Apple Treatment of Diarrhea in Pediatric Practice—Borovsky emphasizes that the raw apple diet as a treatment for diarrhea in infants and young children deserves much more attention than it has heretofore received in this country. He reports twenty-three cases of enteral and parenteral diarrhea with uniformly good results within fourteen to forty-eight hours after the institution of this treatment. The youngest patient was 15 days old and the smallest weighed 4 pounds 12 ounces (2,155 Gm). The acute diarrheas are the quickest to respond with firm stools. This diet must exclude all other foods except weak tea or water. This treatment has a definite place in the management of diarrhea cases especially when medication is refused or is difficult to administer. The beneficial effects of the raw apple in these cases is probably due to the adsorptive power of the apple pulp, the malic acid, the pectins and possibly the tannates. No other single therapeutic measure has so simply and uniformly corrected such diarrheas as are here reported.

Cardiac Emboli—Gethner shows that embolism will produce symptoms which simulate various other diseases, the real condition often being overlooked. He thinks that the possibility of embolism should always be suspected in the presence of heart disease, especially when there is an associated auricular fibrillation, when there was a recent operation in the presence of phlebitis, puerperal sepsis or following quinine medication. In discussing the use of drugs in emboli, he takes up the action of digitalis and quinine. He lists the following as the contraindications to the use of quinine: 1 Cases in which there is congestive and distressing heart failure. 2 Badly damaged hearts—myocardial degeneration and arteriosclerosis. 3 History of previous embolism. 4 Active acute or subacute bacterial endocarditis. 5 Fever. 6 Multiple valve lesions. 7 Disordered conduction such as partial or complete heart block. 8 Fibrillation of long standing. 9 Coronary diseases of the heart. 10 If the patient has not had a previous course of digitalis. 11 In combination with digitalis. 12. If the patient is not confined in a hospital where the action of the drug can be watched. 13 After one course of quinine that did not succeed in restoring normal rhythm. The indications for the use of quinine are but few. It may be tried in paroxysmal auricular tachycardia to prevent the recurrence of an attack. The dose should be fractional. It may be used also for symptomatic relief in auricular fibrillation provided none of the factors enumerated under contraindications are present. Auricular

flutter preceding the normal rhythm may be the real cause of embolus formation. It is best not to try to cure the patient of auricular fibrillation by employing drugs, especially when the condition is of long standing.

Fat Feeding in Schizophrenia—Brice says that the rationale of raising the level of the blood fats in schizophrenia has been fairly definitely established. He mentions the observations of Mott, Stenberg and Duncan and points out that he himself found that in schizophrenia there is a real depression of level of the blood cholesterol, unsaturated and total fatty acids and glutathione below the norm, and that statistically a greater significance attaches to the depression of glutathione and of the fatty acids than to that of the cholesterol. He also adduced evidence supporting the conclusion that the correlation between emotional phenomena and the level of the blood unsaturated fats is closer than that existing between the emotional state and the level of the total blood fats or blood cholesterol. With such considerations and the generally recognized fact that schizophrenic patients are emotionally flat as a background, an effort has been made to elevate the level of the blood fats in a schizophrenic group through an increase of fats in the diet. The group of eleven patients selected consisted of three extremely stuporous and apathetic catatonic patients, three stuporous apathetic patients carrying hebephrenic diagnosis, four actively hallucinated hebephrenic patients and one actively delusional paranoid patient. The diet was based on the observation of Man and Gildea that a balanced meal containing at least 0.6 Gm of fat per kilogram of body weight and with carbohydrates and proteins slightly exceeding the weight of fats could be ingested by normal men and women without causing discomfort or nausea. The increase of fats was given in the

form of additional butter, cream, milk eggs, meat fat and vegetable fats in the salad dressing. The diet was built up progressively. The final twenty-four hour diet thus attained consisted of protein 72 Gm, carbohydrate 130 Gm and fat 78 Gm. The total calories of this diet averaged approximately 2,400. Specimens of blood for determination of serum cholesterol, iodine absorption, total fatty acids and blood glutathione were taken before breakfast at least once each month from each patient. When after four months of fat feeding no appreciable elevation of the blood chemistry had been effected castor oil in one ounce daily dosage was added to the diet and several weeks subsequently acidophilus milk in liberal quantities as suggested by Ingram. No ketosis was produced by this diet. No elevation of the blood chemistry level was effected. No marked changes in weight of any of the patients occurred. No significant mental or emotional change in any of the patients was recorded. During the seventh month of fat feeding, specimens of feces were obtained from each patient and the total lipins were estimated. The figures so obtained were compared to those of an exactly similar series from the same number of general medical and surgical patients on ordinary hospital diet and showed that the schizophrenic patients were eliminating almost exactly twice the amount of the fecal fat of the general medical and surgical patients that is to say, schizophrenic patients on a 178 Gm fat diet had a fecal fat content of 84 per cent, while general medical and surgical patients on a 122 Gm fat diet had a fecal fat content of 42 per cent. It will be noted that proportionately to the dietary intake the excretion of fecal fat by the schizophrenic group should have been but 61 per cent instead of 84 per cent as found. This observation is considered evidence suggestive of anabolic hypofunction in schizophrenia.

Fracture Through Tibial Epiphysis During Period of Growth—According to Morris and Downing vertical fractures through the lower tibial epiphysis sustained during the period of bone growth are comparatively rare. This type of fracture is an entity comparable to Pott's or Colles fracture. The mechanism of its production is always the same and the resultant deformity varies only in degree in each individual fracture. The authors show that the slowly developing deformity is due to the arrested growth of the medial portion of the tibia, resulting from destruction of epiphyseal plate cells. In describing the history of a boy, aged 8, the authors show that the initial treatment of this type of fracture is careful manipulation and

immobilization. Repeated violent manipulations or open reduction for the purpose of procuring exact replacement of the fragments is contraindicated because by so doing there may be further destruction of the epiphyseal plate cells. The indications for operative measures to correct this deformity before the completion of bone growth are (a) instability of the ankle or knee or (b) an increase in the severity of the secondary deformities of the knee and spine. They describe an operation that corrects the deformity and maintains the normal length of the leg. The lower third of the right tibia is exposed by an incision $4\frac{1}{2}$ inches long, parallel and lateral to the crest of the tibia. The periosteum is incised in the line of the skin incision and separated by blunt dissection from around the tibia. About 1 inch above the lower epiphyseal line of the tibia the periosteum and interosseous membrane are divided horizontally. A step osteotomy is done on the tibia, leaving 3 inches between the steps and the lower step about $1\frac{1}{2}$ inches above the lower epiphyseal line. A simple osteotomy of the right fibula is done through an incision $1\frac{1}{2}$ inches long over the outer side of the leg. The upper and medial corner of the lower fragment is removed to prevent too great pressure on the soft tissues of the leg when the foot is put into a corrected position. With a hand drill three No 30 hardened steel pins are inserted—one through the os calcis and the other two through the upper fragment of the tibia just above the line of incision. The two upper pins are parallel to each other and at right angles to the long axis of the tibia. The lower pin is at right angles to the vertical plane of the os calcis. The periosteal tube cannot be sutured over the bone. The wound is closed with interrupted plain catgut for the subcutaneous tissue and black silk for the skin suture. The three pins are fitted with a leg lengthening apparatus, which is set to hold the foot in a corrected position under slight tension.

Retention of Iodized Oil in Fallopian Tubes—Rubin points out that, if the tubes were closed before iodized oil was injected into them they remain closed and the patient suffers no appreciable loss of her chances for conception. If the tubes are perfectly normal before the iodized oil injection, the chances are that they will remain patent, as peristalsis may be relied on to expel the oil into the peritoneal cavity or into the vagina.

When the tubes are constricted intrinsically or extrinsically by agglutinations of their mucosa or serosa the oil can be retained and serves to complete the blockade. The oil is retained in the tubes because of two factors (1) impaired tubal function and (2) the viscosity of the iodized oil. In the presence of a stricture, peristalsis is as a rule reduced and hence is inadequate spontaneously to force the iodized oil through the tight point. It has been demonstrated that greater force is necessary to inject iodized oil through the same tube than water or gas, and this is especially true when the lumen is strictured. The pressure required for the gas to pass such a narrow lumen is frequently as high as 160 or 200 mm of mercury when carbon dioxide is employed and greater when iodized oil is used. The force of tubal contractions can be measured in millimeters of mercury. The contractions range at the maximum between 50 and 60 mm of mercury. Assuming that vigorous antiperistaltic contractions may reach a pressure of 100 mm of mercury, they would not be strong enough to force all the retained oil through the stricture. The author describes cases in which he observed iodized oil retention. These cases and several others in which infection followed iodized oil injection caused him to proceed very cautiously with its use, limiting it to the occasional patient in whom an operation was considered. However, without exhibiting frankly inflammatory signs and symptoms, the retention of iodized oil may induce a local irritation and foreign body reaction which has a definitely deleterious effect in partially strictured tubes leading to permanent occlusion. This is illustrated with case histories. The pathologic conditions found were inspissation, foreign body giant cell infiltration, and closure of the lumen. This lesion is almost identical with the lesion produced by gonorrhea and tuberculosis, from which it must be differentiated. The result is sterility. The author reaches the conclusion that, until a radiopaque substance shall be available having the proper viscosity and density to demonstrate permeable tubal strictures and possessing that degree of resorption which leaves no residue within the tubal lumen after a few hours, thus preventing foreign body reaction, it would be well in instances of sterility to stop using iodized poppy-seed oil and other iodized oils whose chemical composition is more or less the same.

Esophageal Diverticula—Following a review of the earlier literature on esophageal diverticula Howard discusses the etiology, symptomatology, diagnosis and treatment of this condition. He then gives brief histories of seven cases, which came under his observation in the last two years. The patients were from 65 to 78 years of age the average age being 72.3 years. Symptoms were present for from four months in one case to twelve years in another. The average time symptoms were present was 4.33 years. The five patients operated on made uneventful recovery without complications and were entirely relieved of the distressing condition. The author thinks that esophageal diverticula are probably more common than ordinarily thought and that dissemination of knowledge concerning the typical symptom will result in more cases being diagnosed. The two stage operation has proved entirely satisfactory in his hands.

Encephalitis Virus—Armstrong and Lillie found that normal mice, when intracerebrally inoculated with the St. Louis type of encephalitis virus, usually developed a clinicopathologic picture pointing predominantly to a brain localization. Partially immune mice, when intracerebrally reinoculated after a suitable interval, with a proper dose of virus, tended to develop symptoms and disturbances pointing predominantly toward a cord localization. The pathology is that of a destructive inflammation of the gray substance. The authors failed to produce the predominantly myelitic symptoms when the second inoculation was made by the intranasal route. The paralyzes may be permanent or undergo variable to apparently complete recovery. These observations are probably best explained by assuming that cord cells of mice are relatively more susceptible to the virus of encephalitis than are the brain cells and therefore require a higher degree of immunity to afford protection when once the cord is reached by the virus. The possibility of a difference in response by brain and cord cells to active immunization cannot however, be ruled out.

Management of Cervical Metastatic Epidermoid Carcinoma—Clarkson and Barker demonstrate that the high mortality rate from carcinomas of the upper mucous membranes is largely the result of a lack of proper treatment of the areas of lymph drainage by many physicians who attempt

to treat the primary lesions. Preoperative irradiation should always precede biopsy and all other forceful manipulations of the primary lesion. The possession of a thorough knowledge of the various methods of treatment, of adequate knowledge of tumor pathology and of sufficient courage to be scientifically radical are absolutely essential when treating cancer. Careful attention must be paid to the lethal dose of radiation for the various types of neoplasms, and, whenever indicated, the irradiation must be carried to the limits of tissue tolerance. The radiosensitivity of an epidermoid carcinoma increases in direct proportion to the amount of anaplasia, and this rule probably holds true of all neoplasms when considered separately within their own histologic classification. Therefore, sections should be taken from various parts of the primary growth to insure accurate grading and the direction of treatment accordingly. Prophylaxis is left to external irradiation alone. All patients with metastatic nodes are treated principally by a combination of external and interstitial irradiation. The operable nodes that may then remain are removed by means of an endotherm. Radical surgery is resorted to only in operable cases of melanomas and grade I carcinomas with extensive metastases. In cases of infection, small daily doses (100 roentgens) of external radiation should be given first for about ten days, pus collections should be evacuated with an endotherm and, in cases in which implantation therapy is used, removable seeds are advised because the strings facilitate drainage. Insulin and vitamin concentrates will improve the appetite and general condition of cancer patients, but no one can be certain at the present state of our knowledge that malignant cells are not likewise stimulated. Therefore, for the present it may be well to confine their use to diabetic patients and to nondiabetic patients in a state of extreme inanition.

Treatment of Benign Uterine Hemorrhage by Irradiation—So far as Quiney's own experience is concerned, the use of external irradiation by means of roentgen rays is entirely satisfactory in the treatment of benign uterine hemorrhages, so that he now rarely uses radium, thereby avoiding the surgical procedure necessary for its intra-uterine application. He shows that irradiation is undoubtedly the treatment of choice in cases of menorrhagia of the menopause associated with fibromyoma. It yields extremely satisfactory results in cases in which the fibromyoma does not exceed in size a four months pregnancy and in cases of a fibrous uterus in which the possibility of malignancy has been eliminated by the history or by a curettage. In cases of hemorrhage at or near the menopause it is considered proper by many radiotherapists to irradiate as for malignancy. Every attempt should be made however, to eliminate malignancy by a bimanual and visual examination of the cervix. In treating uterine fibromyoma it is immaterial whether the tumor is submucous, interstitial or subserous. A pedunculated fibromyoma is not considered suitable for treatment. A degenerating or strangulated fibromyoma should be removed by surgical procedure, unless there are very definite contraindications to an operative procedure. Fibromyomas of such dimensions that they extend above the umbilicus, or those causing pressure effects, should also be removed surgically. Pelvic infections are a definite contraindication to the use of radium, but this statement does not so strictly apply to the use of the roentgen ray. It has been the author's custom to treat through four 15 by 15 cm areas two anteriorly and two posteriorly, the central beam being directed to the uterus and ovaries. The method employed is that advocated by Weatherwax using 200 kilovolts, 5 milliamperes, 0.5 mm of copper with 1 mm of aluminum, and 650 roentgens in the center of the pelvis. At each sitting, 200 roentgens is given over each area the loss of each interval being made up until the desired number of roentgens has been delivered to the uterus and ovaries. In establishing a premature menopause in the manner described, it should be stated that the patient does not escape the symptoms which usually accompany this change.

Gonorrheal Endocarditis with Amyloidosis—According to Pilcher, cases of endocarditis diagnosed as being of gonorrheal origin can be roughly divided into three groups. 1. Those cases in which blood cultures or cultures taken directly from vegetations at necropsy are positive for gonococci can be considered proved. 2. Cases in which there is a definite history of preceding gonorrheal infection, and in which smears from vegetations show gram-negative diplococci, can be considered strongly presumptive. 3. Other cases in which an endocarditis follows an acute gonorrheal infection but in which no bacterial evidence is obtained can be considered no more than probable. The author reviews the literature of gonorrheal endocarditis and reports in detail one of his cases in which the occurrence of amyloidosis, apparently as a result of the infectious process, is worthy of note. Amyloidosis is rather common, and about 80 per cent of cases are due to chronic tuberculosis of lungs or bone. The other most frequent causes of amyloidosis are chronic osteomyelitis, suppurations, syphilis, leukemia and multiple myeloma. The chief point of interest in the reported case is that as far as can be determined by a careful search of the literature, there is no other case on record in which amyloidosis was caused by gonococcal endocarditis and septicemia. In the absence of tuberculosis or any other of the usual causes of amyloidosis, it is fairly certain that the infectious process caused the condition in this case. There is small chance that the amyloid deposition had begun before the endocarditis, the patient being a normal healthy young man. This brings to attention another point of interest that is the huge deposition of amyloid in this case must have taken place in five months. Although there are no expressions of opinion in the literature as to how long a period is required for the development of amyloidosis, it is usually considered to be a more long-continued process.

Treatment of Intestinal Toxemia with Castor Oil—Schoenbaum and Moomaw show that the colon is the principal focus of infection in toxemia and should receive at least as much attention as the teeth tonsils and other structures. Many constitutional disturbances as well as those of the abdominal cavity have their origin in a toxic condition of the enteric tract. In this connection the author mentions nervous, hepatic, biliary circulatory and respiratory disorders, anemias, rheumatism, arthritis disorders of the skin, backache and other disturbances. He says that the so called normal flora of the intestinal canal may assume pathologic activities under favorable conditions. The colon bacillus is the agent most frequently responsible for nongonorrheal infections of the genito-urinary system. Measures aimed at the detoxification of a septic colon will often help in solving a difficult diagnostic problem. The theory of intestinal toxemia is supported by clinical experience. In discussing the treatment, the author presents evidence on the detoxifying effect of castor oil and its conversion product sodium ricinoleate.

High Right Transverse Abdominal Incision in Congenital Pyloric Stenosis—Brunkow outlines a technic in the surgical management of congenital pyloric stenosis. He emphasizes the following points: 1 Supplying adequate tissue fluids by hypodermoclysis and blood transfusion before operation is done. 2 Providing carefully controlled local heat to the baby's body and warmth in both the nursery and the operating room and recognizing the fact that a 4 Kg infant's heat radiating surface is proportionately twice that of a 72 Kg adult. The smaller the baby the greater the proportionate surface area. 3 Further avoiding body heat loss by keeping the baby under cover during the application of restraints and by eliminating the refrigeration of ether and alcohol baths as a part of the abdominal skin preparation. 4 Employing local anesthesia because it is considered safer than inhalation anesthesia for starving babies. 5 Employing a high right transverse abdominal incision for the Rammstedt operation as an aid in the local anesthesia method as well as providing a wound less likely to permit evisceration during convalescence. 6 Maintaining near perfect hemostasis and remembering that a 4 Kg baby's blood volume is one-eighteenth that of a 72 Kg adult and that consequently the total blood loss allowed in an infant should be eighteen times less than that resulting from an abdominal operation in an adult.

Excretion of Urinary Porphyrin in Rheumatic Fever—The present investigation was undertaken by Kapp and Coburn to determine the type of porphyrin excreted in acute rheumatism and to study the relationship of porphyrinuria to activity of the rheumatic process. Their attention was confined to urinary porphyrins which were detected and identified by spectroscopic examination of ether extracts. In summarizing the results of their studies they state that: 1 The urine of patients with rheumatic fever contains abnormally large amounts of coproporphyrin qualitatively indistinguishable by visual spectrometric methods from the porphyrin normally present in the urine of healthy persons. 2 Coproporphyrin isolated from the urine of rheumatic patients has been provisionally identified as isomer III. 3 The urine of rheumatic patients nearly always contains part of the coproporphyrin in combination presumably with a metal. This combined porphyrin has been observed only sporadically in urines from other sources. 4 The increase of urinary porphyrin appears concurrently with the symptoms of rheumatism. There is no increase following recovery from hemolytic streptococcus throat infections in the absence of a rheumatic attack. 5 The porphyrinuria of acute rheumatism is therefore related to the rheumatic process itself and not to the preceding respiratory infection. The authors discuss the possible significance of these observations.

Treatment of Hemorrhage—Wood asserts that the recent introduction by Marriott and Kekwick of continuous intravenous blood transfusion has provided a new weapon for the treatment of hemorrhage. Patients with hematemesis and melena have been selected, and although there is as yet not sufficient evidence to show the indications for operation in these cases, it is felt that a strong plea may be advanced for continuous blood transfusion as a valuable aid in treatment. At the beginning of the present investigation patients were given large volumes of dextrose (from 2 to 5 per cent) and physiologic solution of sodium chloride intravenously by the continuous drip method. The fluid was allowed to run in at the rate of 4 or 5 ounces (120-150 cc) an hour, and the administration was continued for from one to three days. A moderate improvement was noted in most cases. It has been shown however that dextrose and sodium chloride both diffuse rapidly through the capillary walls and that dextrose-saline solutions are therefore very inferior to citrated blood in maintaining the restored blood volume after a large hemorrhage. If given in excess they would contribute to the edema. Moreover the transfusion of saline solution and dextrose produced no rise but occasionally a slight fall in the percentage of hemoglobin and it remained at a low level for a week or more. Occult blood often persisted in the stools, showing the presence of an ooze from the damaged vessel, which retarded the rise in hemoglobin. The blood urea usually remained elevated for several days and then, in cases in which recovery occurred, slowly fell. In the fatal cases a further rise took place prior to death. Finally there was a marked tendency for the hemorrhage to recur unless the vessel was ligated surgically. When the contribution of Marriott and Kekwick appeared, their methods were adopted with minor modifications in the technic of administration. Citrated blood was given at the rate of from 90 to 150 cc an hour and the hemoglobin was slowly elevated to more than 70 per cent in from twelve to forty eight hours. After the transfusion was finished the hemoglobin sometimes tended to fall slightly, but finally it rose toward normal. The dramatic changes observed during the continuous transfusion of blood have been described by Marriott and Kekwick, and the present study confirms their reports. A series of cases are described illustrating changes in mental state, hemoglobin percentage and blood urea. It is suggested that the changes in height of the blood urea indicate the extent and rapidity of gastro intestinal hemorrhage and aid in prognosis and treatment.

Effect of Toxic Substances on Blood-Forming Organs—Wits finds that the toxic effects on the blood-forming organs of drugs, such as aminopyrine, neosarsphenamine and gold compounds are usually the result of idiosyncrasy and occur with doses that are well within the ordinary therapeutic limits. In certain cases the patient becomes sensitized to the drug and an allergic type of response occurs. Considerable hardship may result from failure to realize the small dosage that may be

responsible for damage to the bone marrow in predisposed individuals, the long incubation period, and the protracted duration of the lesion. The lesions produced in the marrow are briefly reviewed and classified under the headings of regenerative hyperplasia, dysplasia, neoplasia and aplasia.

Atabrine versus Quinine—Flack and his associates made a comparison between atabrine by injection and quinine as antimalarial drugs. The numbers are too small to draw any definite conclusions, but it appears that atabrine by injection acts better than quinine in controlling the clinical symptoms and freeing the peripheral blood of parasites. It is more effective than quinine in subtertian malaria but has hardly any advantage in benign tertian malaria. It has no influence on the sexual forms of the parasite. It has less effect on splenic enlargement than quinine. Complications are negligible. The doses recommended by the makers are adequate for the type of coolies they deal with. As a practical proposition in a tea estate with considerable malaria it is at present too expensive a measure, but for European and Indian staffs they consider it the most reliable drug for subtertian malaria.

Boric Acid as Selective Bacteriostatic Agent—Working with boric acid in the presence of a fermentable substance, Blair found that while it shows a marked degree of selectivity,

suppressing most strains of *Bacillus lactis-aerogenes* while allowing a profuse growth of most *Bacillus coli* strains, it is not unusual to find a strain of *Bacillus coli* which is susceptible or sensitive to the action of boric acid in a concentration of 0.5 per cent, or a strain of *Bacillus lactis-aerogenes* which can tolerate boric acid to this extent. A means of overcoming this difficulty can, however, be found when boric acid is used in conjunction with sodium sulfite. By the addition of sodium sulfite to a lactose boric-acid peptone water, it is possible by a suitable combination of these two chemicals to overcome to a large extent the overlapping that occurs in the results when boric acid is used alone and by this means to make possible a more definite line of demarcation between these two organisms. In a medium consisting of 100 cc of 1 per cent peptone water, 0.25 Gm of lactose, 0.5 Gm of boric acid and 1 Gm of sodium sulfite (anhydrous), the growth of *Bacillus coli* is but little hampered while that of *Bacillus lactis-aerogenes* is inhibited. The medium has been tested on some 494 strains of lactose-fermenting organisms. 450 strains isolated from specimens of water, thirty-six from separate samples of human feces, five from the excreta of cattle, one from a milk supply, one from a specimen of urine and one from a specimen of vomit. The author found that the medium has a marked selective action. It gives satisfactory readings within twenty-four hours of incubating at 37 C. The author is of the opinion that all strains capable of growth in this medium may be regarded as of definite sanitary significance, they are most likely of fecal origin, while those which fail to grow are of minor sanitary importance. He hopes that the boric sulfite test may prove a useful adjunct to the bacteriologic examination of samples of water.

Rapid Method of Measuring Erythrocyte Diameters—

Hynes and Martin describe a method of producing a diameter distribution curve of erythrocytes which permits direct measuring of cell images without pencil outlining. The optical system that they employ consists of a powerful source of light, a 100 candle power Pointolite contained in a light-proof box. The light is condensed by a lens system on the mirror of the microscope as a one-twelfth inch oil immersion lens and a $\times 20$ eyepiece being used. Extraneous light is excluded by a conical black cloth shield. Magnification varies with the distance of the screen from the eyepiece of the microscope and is controlled by a shelf adjustable for height and by three adjustable screws bearing the screen. It is rapidly established by incorporating a micrometer scale in the eyepiece of the microscope and using a stage micrometer in conjunction. Supposing that x divisions of the eyepiece micrometer equal 0.05 mm. on the stage micrometer using the lenses stated then the image of these x divisions projected on the screen must equal 10 cm at 2,000 magnification. Alternatively the image of the stage micrometer may be

projected on the screen and measured directly. To avoid distortion of images, the screen must be truly horizontal and cells in the middle of the field must be measured. Erythrocyte measurement by this method depends on the assumption that the mean diameter of an erythrocyte, whatever its shape, is the same as the diameter of a circle of equal area. With circular erythrocytes the estimation is simple, with poikilocytes it is necessary to find a circle on the protractor such that the area of the erythrocyte outside the circle is equal to the area of circle unfilled. With a little practice it is possible to select the appropriate circle with surprising speed and accuracy. The authors demonstrate that by the use of this method the mean diameter and cell area figures may be obtained with a high degree of accuracy. The practical differences in result as compared with those obtained by the Price-Jones technic are negligible. The considerable saving of time by the use of this technic justifies its use in routine hematologic work.

Influenza Infection of Man from Ferret—Smith and Stuart-Harris report that, forty-five hours after contact with suet ferrets, Stuart-Harris went down with a typical attack of influenza. Throat and nose washings were taken twenty-four hours after the onset and again on the fourth and fifth days of the illness. In each instance the washings were ground in a mortar with a little quartz powder to break up shreds of mucus and then centrifugated. The supernatant fluid was used for the animal tests. Blood was also withdrawn on the fourth day when the patient's temperature was at its maximum, citrated and tested on a ferret. Fortunately samples of the patient's serum, obtained a few months before his illness were available. Further samples were obtained on the third, eighth, sixteenth, thirty-first, forty-fourth and eighty-first days after the onset of symptoms and titrated by the mouse protection test. The technic of antibody titration used was identical with that described by Laidlaw and his co-workers. The results show that the patient possessed no demonstrable neutralizing antibodies against human strain virus at the time of infection. Following the illness there was a steady rise of antibodies. It is possible that they began to appear as early as the third day when the nasopharynx still contained virus. There is no doubt that a decline of circulating antibodies had set in by the forty-fourth day, but experiments suggest that this decline is very gradual. Another experiment shows that the patient had antibodies against the swine strain of virus prior to his illness. It is not surprising that these were of no avail in preventing his infection in view of the total failure of the standard swine strain serum to prevent mouse infection with the strain of virus recovered. Although the patient was engaged about the time of infection in collecting material from cases diagnosed as influenza the later clinical and bacteriologic investigations led to the conclusion that the epidemic disease was no influenza. The animal tests of the samples collected fully confirmed this conclusion. The patient's nasopharyngeal washings reacted with infected mice, producing at the onset in all the animals isolated extensive lung lesions. The fact that animal passaged strains of influenza virus may retain their infectivity for man is of some practical importance. Heretofore no attempt has been made to immunize laboratory workers exposed to infection but it is considered that the time may have arrived when this should be done in the case of those who are

demonstrable virus neutralizing antibodies. It is quite conceivable that a case of laboratory infection might be the starting point of an epidemic.

Sodium Chloride in Diphtheria—Maclean gives an account of an investigation carried out in Ruchill Hospital, Glasgow, in cases of diphtheria to observe the effect the administration of sodium chloride would have on the results of treatment. The cases were divided into four main groups according to the severity of the acute stage of the illness. Each patient admitted to the diphtheria wards was placed in one of two series. The first was treated in the usual manner employed in the hospital; the other received a definite additional ration of sodium chloride. In groups I, II and III, sodium chloride was administered to each patient in one series in the form of a teaspoonful of common salt by mouth three times daily for the first three weeks of hospital residence. All the patients in these three groups recovered. In group II the better results occurred in the cases in which extra sodium chloride was given, but again there was nothing significant. In group III the better results were noted in the series of cases in which extra sodium chloride was given, and there was distinct statistical significance in these results. It is noteworthy that this was so in spite of the tendency in group III for a greater proportion of the cases to be of a less severe type in the acute stage in the series in which extra sodium chloride was not given than in the other series. A number of patients in group IV were given salt by mouth as in the other groups, in others the method employed was to administer daily for a period of three weeks after admission 30 cc of 5 per cent saline solution intravenously slowly through a hypodermic needle. In a third set of cases in which the acute stage was of a more critical nature and feeding by mouth was precluded by vomiting, continuous rectal dextrose saline solutions were given and maintained until signs of acute toxemia had passed off. Taking group IV as a whole, a definite, though insignificant improvement is shown in the series of patients who received extra sodium chloride. Consideration of these results leads to the conclusion that the administration of extra sodium chloride to a series of patients with diphtheria is associated with an improvement as compared with a series that does not receive extra sodium chloride. The author points out that the observation that the administration of sodium chloride to patients with diphtheria is associated with better results is in accord with expectations if the view is accepted that in diphtheria there is a considerable deficiency in the secretion of the adrenal cortex. In support of this view it has long been recognized that adrenal hemorrhage is common in fatal diphtheria. Definite evidence has not yet been produced of the value that injections of adrenal cortex extract would have on the acute stage of diphtheria, and with the present prohibitive cost of potent extract an adequate trial would be very expensive. It seems, however, that sodium chloride is distinctly beneficial

Changes in Intervertebral Disks Following Lumbar Puncture—Milward and Grout relate that during the last two years five patients attending the Chesterfield Royal Hospital who had been operated on under spinal anesthesia complained at varying intervals after operation of pain in the back and occasionally of pain in the lower limbs. The roentgen examination revealed in all definite and progressive changes localized in one intervertebral joint. All complained of severe pain in the back, either partially or completely preventing them from walking or sitting up. All showed on examination that the lumbar spine was held rigid by muscle spasm in the flexed position. There was marked tenderness over one or all the spinous processes of the second, third and fourth lumbar vertebrae. In one patient the fully developed lesion was accompanied by retention of urine. In two cases there was intermittent backache of a mild character during the latent period. The roentgen exami-

nations all showed more or less similar changes: (1) a progressive arthritis localized to one intervertebral joint, (2) loss of joint space, (3) rapid progress of the lesion and (4) new bone formation linking up the articular edges of the bodies of the adjacent vertebrae. When the condition was recognized, the treatment adopted was fixation of the lumbar spine in extension with a full length ambulatory plaster jacket as for compression fractures. The authors think that the most satisfactory theory is that suggested by Pease—that the condition is due primarily to injury to the intervertebral disk, with secondary changes in the vertebral bodies. Pease suggested that the needle actually bored a hole in the annulus fibrosus through which the nucleus escaped. This would seem possible in children and would explain the early loss of joint space and the progressive nature of the lesion. Although it is conceivable that such a process may take place in the adult, the more likely explanation is that the trauma resulting from the impinging needle in the fibrous ring causes an inflammatory reaction with a consequent weakness in the fibrous wall permitting of a gradual escape of the nucleus pulposus. This is borne out by the x-ray appearances in three of the cases.

Testing Antituberculosis Vaccines—Berg points out that a standard or official method of testing a proposed antituberculosis vaccine is not available at present. Outlines are offered with the hope that other workers will revise them. A workable plan will then have been evolved which will enable workers in different laboratories to test the same vaccine by the same method. The author says that until recently the "longevity test" seemed the method of choice. In a second method lately used, principal animals and controls are killed at the same time after

infection and the character and distribution of lesions are compared. It is claimed that this 'lesion distribution test' correlates well with the longevity test. However, since physicians will expect a proposed vaccine to protect children against the effects of accidental reinfection as evidenced by greater longevity, the lesion distribution test is not applicable here. The author describes a longevity test with guinea-pigs. In his proposed method of testing antituberculosis vaccines the main points are: (1) selection of a highly virulent strain of human tubercle bacillus through virulence tests in cooperating laboratories; (2) use of two infection doses small in weight but sufficient to kill all controls in about 100 days average; and (3) statistical interpretation of the difference between mean (or average) days of life of immunized and control animals.

Liver in Alcohol Polyneuritis. M. Villaret, L. Justin Besançon and H. P. Klotz —p. 1159

Gastric Disorders in Alcoholic Polyneuritis.—Villaret and his collaborators call attention to the early appearance, constancy and other specific characteristics of gastritis accompanying alcoholic polyneuritis. Some gastritis was in fact observed in fifty of their cases of polyneuritis. Furthermore it preceded the appearance of the neuritis in all instances, occasionally by a few weeks but more often by several months. In forty-five of the fifty cases it was possible to note an abnormality of the gastric secretion. This was always in the same direction and consisted in achlorhydria (thirty-three cases) and a marked hypochlorhydria (twelve cases). When gastroscopic examination was performed early enough definite lesions of the stomach were seen. Most frequently this consisted in an atrophic gastritis which was especially characterized by a shallowness of the folds of the stomach. Furthermore, the motility of the stomach, which was especially active in the slight cases, was absent or practically absent in those with advanced atrophy. It was also noteworthy that improvement of the gastritis preceded that of the neuritis and that it was possible to observe a normal gastroscopy during persistence of the neuritic lesions.

*Anesthetic Infiltration of Thoracic Chain. P. Wertheimer and A. Trillat —p. 1356

Anesthesia of Thoracic Chain.—Wertheimer and Trillat impressed by the inconstancy of effect produced by infiltration of the stellate ganglion as compared with that of the lumbar region, attempted an investigation of the anatomic relations and improvement in technique that might favorably affect the results. Two conditions are necessary to make it possible to infiltrate correctly a sympathetic chain or a ganglion. The first consists in determining the serous landmark by which the needle may be placed at the edge of the ganglion. The second presupposes a soft cellular tissue allowing the injected liquids to bathe the nearby nervous elements. These two conditions are realized by the upper segments of the thoracic chain. The point for penetration of the needle is situated from 5 to 6 cm. from the summit of a spinous process. The needle traverses the second intercostal space. It is well to infiltrate the superficial tissues by an injection made with a fine needle, since this avoids the pain of passing the larger needle through the cutaneous tissues. The needle is directed forward and a little down to a depth of from 2 to 3 cm. and is halted by bony contact. The point of the needle is then against the neck or the head or the rib or on the lateral face of the vertebral body. The needle must be withdrawn a few millimeters and from 10 to 15 cc. of solution injected. The latter infiltrates the cellular space surrounding the sympathetic chain. By this technique it is easy to introduce the needle in the desired area and yet to avoid the danger of puncturing the pleura. They have never observed any accidents from this technique. The indications for such treatments may

be divided into painful disorders of the upper limb of phrenic pathologic origin, arteritis of the upper limb and bronchial asthma. In some of these conditions the authors were successful in relieving the symptoms. They were however, especially interested in proving that infiltration of the thoracic chain high up satisfies the technical rules and therapeutic necessities, which infiltration of the stellate ganglion only partially supplies.

Fibroplastic Parietal Endocarditis with Eosinophilia.—On the basis of observations in two cases which had a considerable resemblance, Löffler directs attention to a peculiar disease entity, a fatal, subacute fibroplastic parietal endocarditis of the ventricles (the valves remain free), with severe eosinophilia of the blood but with complete intactness of the pericardium. As the result of the fact that the influx of the blood into the right ventricle is made more difficult by the parietal endocarditis, a stasis develops which resembles greatly that of Friedel-Picks syndrome. In both patients the disease was characterized by the absence of febrile temperatures although there was the possibility of a febrile reaction from pulmonary infarcts in one case. Regarding the etiology the author says that in one case *Streptococcus viridans* was demonstrable but that in the other case all cultural examinations of the blood, the puncture fluids and the organs remained negative.

Polyavitaminosis in Nursing Fed with Fat-Free Dry Milk.—Wieland reports a polyavitaminosis (keratomalacia and Barlow's disease) in a nursing aged 6½ months. Because the parents of the child had an exaggerated fear of milk crusts they had fed the child without a doctor's advice, for six months with a fat-free dry milk. This resulted in an A-avitaminosis (keratomalacia) which was preceded by a latent stage of two months' duration during which the nursing showed no increase in size or weight. The complicating Barlow's disease was probably the result of a lowered vitamin C content of the dry milk preparation and also of an insufficient utilization of the offered vitamin C as a result of the total lack of vitamin A in the food and in the organism. The combined administration of vitamins A and C resulted in complete clinical cure, except that a corneal lesion (leukoma adhaerens) remained on the left eye. The author stresses that this observation represents a new warning against the dangers involved in the prolonged use of special milk preparations intended to be used only for a short time for therapeutic purposes.

*Cerebrospinal Fluid in Vertebral Arthritis. L. Bocchi —p. 273

Cerebrospinal Fluid in Vertebral Arthritis.—Bocchi made examinations of the cerebrospinal fluid in fifty patients suffering from rachialgia in vertebral arthritis. The etiologic diagnosis was beyond question in all cases because the clinical symptoms and roentgenograms which have been previously described as characteristic of vertebral arthritis existed in all cases and hyperemia by means of Bier's hot air treatment and immobilization of the patient gave satisfactory results in the author's cases. The lumbar punctures were harmless and reduced pain. The author states that there are no modifications

of the cerebrospinal fluid in vertebral arthritis. The examination of the fluid is of diagnostic value in cases of rachialgia of doubtful origin. Alterations of the cerebrospinal fluid in rachialgia indicate involvement of the nervous system or of the meninges. The nervous disturbance may cause clinical symptoms of vertebral arthritis in the absence of the latter or they may develop as complications in vertebral arthritis.

Ucko's Test for Liver Function.—Ucko's modified technic for performing the Takata-Ara test is described in the *Comptes rendus des seances de la Societe de biologie* 118 534 (No. 6) 1935. The test is a precipitation reaction produced by mercury in serum of hepatic patients. According to Ucko the test is of diagnostic value in liver diseases. A strongly positive reaction (third degree of intensity reaction) is, in his opinion, an almost certain sign of liver cirrhosis. Cozzutti performed the test in 433 patients suffering from several diseases without involvement of the liver and in eighty-three patients suffering from liver diseases. As a rule it gave negative results in all patients in the first group and more or less positive results in the second. Strongly positive reactions (third degree intensity reaction) were obtained in liver cirrhosis and in syphilis of the liver. In general, the results of the test agreed with those of induced hyperglycemia and also with the clinical evolution of the disease. In some cases the results of an anatomopathologic study verified those previously given by the test. Cozzutti concludes that Ucko's test is of practical value as a preliminary or complementary test for function of the liver, especially that of liver proteosynthesis, but that it is not a specific test for liver cirrhosis.

Variations of Amount of Complement in Blood Serum in Course of Fangothrapy. S. Battistini, A. Robecchi and A. Silvani—p. 205

Eosinophils in Arthritis Under Colloidal Sulfur Treatment.—De Matteis and Verdolini studied the behavior of eosinophilic leukocytes following parenteral administration of colloidal sulfur in patients suffering from rheumatic arthritis and in normal persons. The treatment caused complete eosinophilia in arthritic patients and complete eosinopenia in normal persons. The author believes that the action of colloidal sulfur on eosinophils depends on the reaction of the bone marrow which reaction is in relation with the presence or absence of constitutional sympathetic disturbances. Owing to the presence of constitutional sympathetic disturbances in patients suffering from arthritis, colloidal sulfur causes a reaction of allergic sensitization with consequent stimulation of the bone marrow to an abundant production of eosinophils and eosinophilia. In normal persons, owing to the absence of sympathetic disturbances, the reaction of the bone marrow following the administration of colloidal sulfur is one by which the production of eosinophils is inhibited. The latter reaction accounts for the production of eosinopenia in normal persons, after administration of colloidal sulfur.

Complement in Blood Serum in Course of Mud Therapy.—Battistini and his collaborators found that the amount of complement in the blood serum in the course of rheumatic fever is diminished in 50 per cent of the cases and that there is a parallelism between the amelioration of the clinical symptoms and the increase of the amount of the complement in the blood serum. The authors made determinations of the variations of the complement before and after mud therapy in twenty-six patients suffering from chronic polyarthritis of

different types and from rheumatic fever. The treatment consisted in fifteen applications of thermal muds. The amount of the complement, in patients suffering from chronic polyarthritis, was normal before the therapy and did not change after it. The amount of the complement was greatly diminished (in some cases up to complete disappearance), before the treatment, in patients suffering from rheumatic fever and diminished still more after it. The lower figures were obtained in cases in which the test was performed shortly after subsidence of the acute attack, when the clinical symptoms and sequels left by the disease were still noticeable. The authors believe that their results prove the existence of a relation between complement and rheumatic fever and also between complement and the clinical symptoms of the disease. The diminution of the complement, after mud therapy in patients suffering from rheumatic fever, is caused by a reaction of the organism to the treatment which manifests itself in the reappearance of the clinical symptoms. The results obtained by the authors point out also the sensitivity of the test which showed the changes of the amount of complement paralleling the clinical symptoms, although the latter evolved only to a small degree in the authors' cases.

*Determination of Labor. J. Fontes—p. 283

Determination of Labor.—Fontes reviews the follicular, the corpus luteum, the hypophyseal and other theories advanced to explain the phenomenon of labor. Investigation led him to believe that labor is due to an action exerted by the particular state of the musculature and the uterine innervation at this moment. The distention produced by the egg has undoubtedly a stimulating action on uterine contractions. This distention is similar to that which the blood exerts on the heart. It is, however, impossible to explain the determination of labor simply by uterine distention. The author was able to find an oxytocic substance for the uterus of the guinea pig in the blood of a woman in labor. This substance produces rhythmic and energetic contractions of the uterus for hours. When two horns of the same uterus are placed in oxygenated warmed Ringer's solution in separate containers and to one is added 1 or 2 cc. of defibrinated blood from a woman in labor and to the other the same quantity of blood from a woman not in labor or from a man, this oxytocic action is readily visible. It was also observed that a woman's blood loses this property a few hours after labor ceases. He believes therefore that the placenta perhaps plays a part in the determination of labor. In support of this view he found that placental extracts exert a definite oxytocic action, while muscular extracts prepared with the same technic are ineffective. He injected placental extracts into female guinea-pigs at term and was able to verify the fact that gestation was thereby interrupted.

Surgery in Ovarian Dysmenorrhea. M. Reyes—p. 543

Ozone Treatment in Anthrax.—Pribluda reports satisfactory results from pure ozone of high concentration in the treatment of anthrax. He has treated six patients, some of whom were suffering from grave forms of the disease. The injections, which may be given intravenously, subcutaneously or intramuscularly should be made slowly. For intravenous injections the patient lies at rest after previous administration of morphine and camphor in oil. The quantity of ozone to be injected intravenously varies between 25 and 250 cc. When the injection is made by the intramuscular and subcutaneous routes, an infiltration of the gas is made at the peri-inflammatory zone. The orifice of puncture is covered with collodion to prevent reflux of the injected gas. The quantity of gas to be injected varies between 20 and 400 cc. The superficial application of

ozone is made by means of a funnel covering the anthracic zone and connected with the ozone generating apparatus. This is done in order to contact the inflammatory zone with an atmosphere of pure concentrated ozone, under light pressure, for from five to fifteen minutes. The author concludes that the treatment by ozone is efficacious in anthrax. It results in immediate sedation of pain, great reduction of the evolution period, diminution of the malignant condition of the disease and improvement in the general condition. The treatment is simple, harmless and painless. It can be given to ambulant patients, who are able to resume work shortly after having been treated. The scars left by anthrax treated by ozone are not deforming.

Magnesium Sulfate in Treatment of Cough.—Freyre resorted to hypodermic injections of magnesium sulfate in the treatment of sixty children suffering from asthmatic bronchitis, whooping cough and spasmodic cough of uncertain etiology, with or without vomiting. The dose varies between 1 or 2 cc. of a 15 per cent solution of magnesium sulfate. The injections are given every day or at intervals of two or three days, according to the seriousness of the disease. In all the patients treated by the author (except two suffering from asthmatic bronchitis) the treatment produced antispasmodic and sedative effects that lasted for five or six days. The asthmatic and spasmodic crises and the whooping paroxysms and vomiting were controlled generally from the first injection and the patients began to convalesce after from one to three injections. No patient in the author's group showed signs of general or local intolerance and no complications set in. The treatment is harmless and easy to perform. Cystitis, nephritis and meningitis are contraindications. The development of respiratory paralysis is not likely. It would be the result of an overdose of magnesium sulfate and would indicate an immediate intravenous or intramuscular injection of calcium chloride or a subcutaneous injection of atropine.

- *Peculiar and Not Hitherto Described Phenomenon of Prophylaxis of Measles with Normal Blood F. Goebel—p. 293
Leukemic Articular Symptoms During Childhood J. Kraft—p. 295
Hanganathu Deicher's Reaction in Diseases of Lymph Nodes During Childhood E. A. Voss—p. 299

Prophylaxis of Measles with Normal Blood—Goebel directs attention to the possibility of immunizing against measles by means of normal blood. He reports that a child aged 1 year showed the prodromes of measles, September 27. September 30 he injected 35 cc. of maternal citrate blood into the thigh of the brother aged 5 who had remained extremely delicate after an attack of empyema. During the first few days the boy felt well but on October 7 (the eleventh day of his incubation period) he had fever, a painful swelling of the thigh and enlargement of the inguinal glands. However on the following day the local symptoms had almost completely disappeared and the fever showed no further increase. The day after that nothing more was noticeable and although the boy had not been isolated from his sister he did not develop measles. The author mentions several other cases in which he made similar observations. In discussing the reaction he points out that active immunity against measles is a virucidal immunity. Convalescent serum as well as normal blood has a virucidal action. Aside from the convalescent serum of poliomyelitis, the serum of measles is perhaps the only virucidal serum of clinically demonstrated action. As a rule it intercepts the virus which circulates in the blood and destroys it there without local reaction. In the described cases there developed a local reaction for two reasons: 1. The virucidal antibodies of the injected blood remained entirely or partly localized just as in uninfected measles this binding on the skin produces the cutaneous exanthem in the same manner as it comes to the formation of an area in case of vaccination. In all the cases observed by the author the reactions appeared on the tenth or eleventh day of incubation that is at the time of onset of the prodromes of measles. Since at this time the antibodies of the infected organism commence their activity it is possible that in this process there is an addition of passive and active immunity. The author is unable to give a definite explanation as to why the antibodies remained localized in these cases.

However, he points out that an allergic factor might be involved. (The first two children were from an allergic family.) Moreover, he thinks that the trauma involved in the introduction of relatively large quantities of blood might be of some significance, it may have retarded the resorption.

*Intracranial Hemorrhages in the New Born K. Hoffósi—p. 311
Birth in Knee Elbow Position (Without Support for Perineum) S. A. Freymann—p. 324

Ventrosuspension of Uterus and Its Results—Sigwart says that for a number of years he employed the operation of Doléris in the modification of Bumm. However, this method did not entirely satisfy him. It was his aim to put the uterus as much as possible into the physiologically suspended anteverted flexed position, to see to it that the vesico-uterine excavation would retain its normal basin shape, to prevent adhesions between the round ligament and the long abdominal muscles, and to effect a firm and permanent connection between the ligaments and the fascia. He uses Pfannenstiel's incision. After the uterus has been detached from its adhesions and after the necessary interventions on the adnexa have been completed, so that the peritoneum can be closed, the ventrosuspension is done. He grasps the round ligament on both sides, approximately 3 or 4 cm. away from the uterine attachment, by means of a Kocher clamp. Then he pierces with another clamp the peritoneum laterally to the rectus muscle, where underneath the severed fascia of the internal oblique muscle a small triangle of peritoneum lies free, but he carefully avoids the small vessels passing there. He directs the ligament toward the latter clamp, grasps it and, following removal of the first clamp, he pulls it through the peritoneum. The same is done on the other side. The transverse section of the fascia is so deep downward and so long that the ligament will lie directly in the angle of the fascial incision. Then it can be exactly determined how far the loops of ligament have to be pulled out in order to secure the uterus in the desired suspension. Then the abdomen is closed by a continuous peritoneal and muscular suture. The fixation of the ligaments is done in such a manner that the first three or four of the button sutures, right and left, with which the fascia is closed grasp also the loops of ligament. In this manner the ligaments are fixed securely to the underside of the fascia just as it is done in the Alexander-Adams operation. However this ventrosuspension is not enough for the author, but he combines it with the abdominal vesicofixation. He used this method in 236 cases and shows that it fulfils to a large extent all demands that are made of an operation of this type. The danger of ileus is almost completely excluded the position of the uterus obtained by it is practically physiologic, the result is usually permanent vesical difficulties are practically absent no disturbances result during delivery, and there are no complaints about difficulties at the sites of fixation. To be sure the author admits that a certain percentage of failures must be counted on but the percentage of failures in this operation is considerably below that of other interventions for the correction of positional abnormalities.

Sclerema Neonatorum and Its Treatment with Thyroxine—Schulze says that the treatment of sclerema neonatorum is usually only symptomatic and consists in supplying warmth and in massaging the involved parts. He refrained from massage but gave especial attention to proper warming and general care. He found that only the milder cases responded to this treatment and he decided to try thyroxine in extremely severe general sclerema. The intramuscular injection of thyroxine produced surprisingly favorable therapeutic results. The author mentions various theories regarding the pathogenesis of sclerema and stresses particularly H. J. Mann's experimental demonstration of a disturbance in the

swelling conditions of the connective tissue. His own observations in the course of the thyroxine therapy indicated that the chief factor is a disturbance in the water economy of the skin and of the subcutaneous tissues, for the appearance and disappearance of the scleredema was accompanied by rapid changes in weight. The behavior of the urinary secretion in one case in which thyroxine was used makes the importance of the disturbance in the water exchange even clearer. The author thinks that thyroxine reduces the swelling of the sclerodematous tissue. He is unable to say whether in addition to this a circulatory action plays a part.

Intracranial Hemorrhages in the New-Born—Hollosi maintains that the etiology of intracranial hemorrhages is not uniform. It is probable that in some of the cases a constitutional abnormality is a predisposing factor to hemorrhage. The symptoms of the intracranial hemorrhages vary greatly, only in exceptional cases is it possible to localize the hemorrhage exactly. The treatment of intracranial hemorrhages should be symptomatic. It has not been definitely demonstrated whether the intracranial hemorrhages play a part in the development of diseases of the nervous system during later childhood.

*Treatment and Prognosis of Leukemias Particularly the Favorable Results in Lymphatic Leukemia Involving Only the Spleen I Solomon—p 526

Roentgen Treatment of Actinomycosis—According to Keijser, roentgen treatment is the method of choice in actinomycosis. He employed it in 101 cases in which the diagnosis had been microscopically verified. According to the localization of the lesion, he differentiates (1) the cervicofacial inclusive of the cutaneous actinomycosis (2) the abdominal and (3) the thoracic and other rare localizations. In his material the cervicofacial form was the most frequent (69 per cent). In this form he obtained especially favorable results with a combination of roentgen treatment and of medication with potassium iodide. The potassium iodide was usually administered in daily doses of 6 Gm. Incisions were made only in cases of abscess formation. Greater surgical interventions could be avoided. The number and size of the fields for irradiation as well as the focus-skin distance were individualized according to the extension and the localization of the lesion. Whenever possible, the disease focus was attacked from two or three sides. By the tangential direction of the rays, it was possible to protect the deeper lying tissues to a considerable extent. To be sure in some cases, the irradiation of the deeper tissues could not be avoided but even in these cases the author observed no injurious effects. The aim was always the homogeneous irradiation of the entire diseased area with from 75 to 85 per cent of the unit skin dose. The filter consisted of 0.5 mm of copper and the tension was from 170 to 180 kilovolts. The depth action was adjusted by varying the focus skin distance. This distance varied between 30 and 60 cm. In about 50 per cent of the patients a single series of irradiations was sufficient. If, after six or eight weeks, the improvement was not considerable a new series was given. A third and fourth series became necessary in only a few of the cases. The combination roentgen and iodine treatment was successful in sixty seven out of the sixty nine cases with cervicofacial actinomycosis. The other two patients died. Of twenty-seven patients with an abdominal localization of the disorder nine were cured. In some cases the author resorted to injections with fuadin and he thinks that the fuadin treatment of actinomycosis deserves further attention.

Roentgen Treatment of the Leukemias—Solomon points out that in spite of the comparatively imperfect technique in the earlier years of the roentgen era favorable results of roentgeno-

therapy of leukemias were nevertheless reported as early as 1903 and 1905. However, the favorable results were only temporary although the patients appeared healthy at first and were able to work again, there usually was a relapse after a short time. Renewed irradiations were usually not as effective as the first ones had been, and finally the disease became entirely refractory to rays. However, with the improvements in the roentgen technic, particularly with the harder rays and the more exact dosimetry, the number of entirely refractory cases of leukemia became lessened, although the ultimate prognosis seems not to have improved. The author shows that certain complications of leukemia likewise yield to roentgen therapy. He cites favorable results in leukemic priapism that had proved refractory to other measures and states that the albuminuria of patients with leukemia is responsive to roentgen irradiation. In view of the favorable effects of roentgen treatment on the leukemic albuminuria, it has been suggested that the kidneys be given a systematic irradiation before beginning the treatment of the spleen, bone marrow and glands. In some of the cases that were treated in this manner, the results seem to be better than before this method was adopted. Nearly all authors who employ roentgen treatment have abandoned the larger doses as well as the so-called intensive method and have returned to fractionation and irradiation in series. The number of series and the length of the intervals between them are determined on the basis of the blood status. The author points out that some authors have ascribed the refractoriness to treatment during the later stages of leukemia to the fact that local irradiation is insufficient. Consequently, they have attempted to add general to the local irradiations. However, it was found that the total irradiation likewise failed to effect a permanent cure. Nevertheless, it has certain advantages and is particularly advisable in cases which have such a multiplicity of foci that a local treatment is impossible. It can also be tried in cases in which the local treatment fails. The author calls attention to the comparatively rare form of lymphatic leukemia that is restricted to the spleen. He gives detailed histories of two such cases, in which roentgen irradiation proved especially valuable. The two cases are noteworthy for long survival and for the return to normal on the part of the blood picture.

Metabolism of Diabetic Patients Having Malignant Tumors—Wetzler-Ligeti and Kostenblatt cite investigators who observed that the glycosuria of diabetic patients decreases when a malignant tumor develops and that the sugar content of the blood is increased in patients with carcinoma. They state that they themselves investigated the sugar content of the blood of twenty patients with carcinoma and found thirteen with hyperglycemia, although neither the patients themselves nor their families gave a history of diabetes. The authors also call attention to the fact that several investigators made the observation that in sugar tolerance tests the blood sugar curves of carcinoma patients resemble those of diabetic patients. They themselves observed in the course of several years on a large material of diabetic patients that, if a diabetic patient develops a malignant tumor the glycosuria disappears while the glycemia remains comparatively high. They made this observation in eleven cases. It appeared that the site of the tumor was of no importance. The authors' material consisted of one pulmonary tumor, one ovarian carcinoma, one hypernephroma, one carcinoma each of the colon and of the gallbladder and three carcinomas each of the stomach and of the pancreas. In discussing the pathogenesis of the disordered carbohydrate metabolism in patients with malignant tumors the authors suggest that a disturbance in the oxygen supply of the organism might play a part.

Treatment of Gastroduodenal Hemorrhage—According to Zabludovskiy and Abramson, severe hemorrhage from gastric or duodenal ulcer occurs with much greater frequency in the male patients than in the female. Of the twenty-five cases treated by them, twenty-one were in male patients. They urge that patients be referred to the surgical service at the first signs of bleeding rather than in the stage of a life-threatening hemorrhage. Direct evidence of bleeding, such as a tarry stool or blood in the vomitus may be absent. These signs are not infrequently preceded by a general weakness to the point of fainting, pallor and a weak pulse. There is a tendency to recurrence on the part of those who had one severe hemorrhage. The authors therefore feel that in the presence of definite evidence of ulceration such patients should be submitted to an operative intervention during the quiescent period. In their experience blood transfusion proved to be the most effective means of arresting gastric or duodenal bleeding. It should, however, be given in the early stage and not as a last resort. Patients rendered acutely anemic are poor surgical risks. They can, however be saved as a rule, by a transfusion of from 150 to 200 cc of blood. Fresh or preserved blood was more efficacious than plasma. The aim of transfusing small quantities of blood is to arrest bleeding rather than to treat the acute anemia. The latter is to be met by a transfusion of from 350 to 400 cc. of blood not earlier than from ten to fourteen days after the arrest of the hemorrhage in order to avoid raising the blood pressure. Blood transfusion, however, is not invariably successful. A certain number of patients, particularly those bleeding from a large callous ulcer, will bleed to death. The older patients exhibit less tendency to stop bleeding than the young, presumably because of sclerotic changes in their blood vessels. Operative indication therefore, is more common in patients past the age of 40. Palliative operations, such as ligation of afferent blood vessels suture of the ulcer and cauterization of the ulcer are not effective, and least of all is the operation of gastro enterostomy. Though hazardous for the patient, the most effective procedure is partial gastric resection. The latter must always be preceded by a transfusion of from 350 to 400 cc of blood. The most important element in the treatment is the correct estimation of the limitations of the conservative treatment (blood transfusion) and the timely choice for operative intervention.

Symmetrical Arthropathies in Addison's Disease—Burkens reports that although patients suffering from Addison's disease often complain of arthralgias and neuralgias it is practically never possible to find disturbances of the joints such as limitation of movement or crepitation and the roentgenograms seem to be normal. Curschmann's is the only known communication that describes four cases in which objective disturbances were found. The author gives the histories of three patients with Addison's disease who had also pulmonary tuberculosis and of whom the first presented calcification of the adrenals and progressive symmetrical omarthrits with severe limitation of shoulder movements the second showed progressive and symmetrical omarthrits coxarthrits and gonarthrits with severe limitation of movements of these joints and

the third had progressive and symmetrical inflammation of the shoulder and elbow joints with severe limitation of movement of these joints. All patients presented some degree of atrophy of the muscles connected with the interested joints. The roentgenogram recalled that of rheumatoid arthritis. Periarthritis was present in high degree. The occurrence and simultaneous development of these disturbances with Addison's disease and their symmetrical character make it extremely probable that this is no coincidence but that there is a relation of cause to effect between Addison's disease and this kind of arthropathy.

Monilethrix—Gottlieb describes four cases, in siblings aged from 10 to 21, otherwise apparently normal both physically and mentally. The anomaly, in more or less marked degree, has been traced back through five generations of the family and seems to be transmitted as a dominant characteristic. He says that, according to van Leeuwen and others, the new hair which appears after roentgen epilation or epilation with thallium is normal at the start and by repeated roentgen epilation after the hair has again become deformed a somewhat longer effect has been maintained each time.

- Changes in Cerebrospinal Fluid in Psoriasis and Normal Values for Albumin Content of Cerebrospinal Fluid A V Neel—p 836

Primary Pulmonary Carcinomas—Vosbein tabulates the cases of six men and eleven women who were treated at the Aarhus district hospital from 1920 to 1935. An increase in the number of cases during the last five years is noted. In eleven of the thirteen cases in which necropsy was done there was a tumor of nodular massive form, in four cases believed to have originated from the main bronchus, in two from the large bronchi and in five with uncertain point of origin, in two cases there were tumors of disseminated medullary form. Microscopic examination in eight cases showed typical bronchial carcinoma. Sooner or later in the course all the patients had pulmonary symptoms. The duration of the disease was from one and a half months to two and a half years, or an average of nine months.

Lymphogranulomatosis—Of Raagaard's nineteen cases in which treatment has been given since 1922, eighteen were verified histologically. There were twelve male and seven female patients aged from 11 to 62. In fifteen patients the duration from histologic diagnosis to death was from one to sixty-four months or an average of about sixteen months. All the patients had a chronic course. The primary localization seemed to be in the glands of the neck in seven in the axillary glands in three in the inguinal crural glands which, he says, is rare in three in the abdomen in two in the skin in one in the mediastinal glands in four and in the lungs in one. The glands of the neck were affected in all but one. Enlargement of the spleen was found in only four cases. Pain was a prominent symptom in the material. All the patients were given roentgen treatment of the affected regions. Roentgen treatment is believed to be of great value in alleviating pain. In one of the three living patients a man aged 39 the duration of the disease has been six years. The disorder in this instance was mainly and lies in the last years apparently been exclusively localized in the mediastinal glands. In the case of continued recurrences the effect of roentgen treatment seems undiminished close series appear to be more effective than more scattered treatment. The patient is now practically without subjective symptoms.

THE ORGANIZATION OF A HOSPITAL LABORATORY

ARTHUR H. WELLS, M.D.
DULUTH, MINN.

Reduced salaries, raised census and higher collections have in many hospitals throughout the country created an optimism which has been reflected in a general trend toward an improvement of service. Boards of directors have come to rely on the medical staff for advice of a scientific nature. The time is most opportune for a general realization, especially by the older and more influential physicians, of the now developing possibilities. Many hospital laboratories may be anywhere from fifteen to twenty years behind without its staff fully appreciating this defect. It is hoped to set forth a conception of a modern, efficient, yet unpretentious laboratory for a hospital of moderate size, to serve as a measuring stick for institutions in a similar class.

As in other fields, the personnel of a laboratory is its principal limiting agent. It is conceivable, but unlikely, that a laboratory can be all that could be desired without the full time attention of a clinical pathologist. His reputation depends on what he produces in one institution. There are no outside business affairs or necessary social duties as are found in any part time arrangement. A moderate sized hospital will give him more work than he can possibly do to complete satisfaction. The increasing complexity of clinical pathology is such that the average physician cannot keep up with his own work and the advances in diagnostic aids offered by the laboratory. Consultation of the clinical pathologist on matters pertaining to the application and interpretation of laboratory tests is always available. His efforts will lend additional scientific life and character to the hospital and aid in making it the medical educational center of the community.
